-gating_cells *clock_gating_cells_list*

Specifies that all objects gated by clock-gating cells that are listed in *clock_gating_cells_list* will be nongated, and removes clock-gating cells from the design.

DESCRIPTION

The command identifies and removes clock-gating cells according to the specified option. It actually removes clock gating from objects (registers and clock-gating cells) performed by Power Compiler. The command provides a mechanism to remove clock gating selectively from various parts of the design.

This command also removes redundant clock-gating cells that do not gate any clock-gating cells. Any associated test observation logic is removed during optimization.

All registers that are nongated are remapped to new sequential cells, which might result in new pin names for the registers. A register can be gated by multiple clock gates in a multiple-stage clock-gating design. If the register is nongated, all clock gating on the clock path for this register is removed. However, if you specify to remove only one clock-gating cell, the remaining clock-gating cells will still exist on the clock path of the register.

Pin-based timing exceptions set on the pins of the old register might have been set by the **set_max_delay**, **set_min_delay**, **set_multicycle_path**, and **set_false_path** commands. These exceptions might not be properly transferred during the process if the new and old pin names do not match. The **remove_clock_gates** command issues a

warning message if there are pin-based timing exceptions on the register to be nongated.

EXAMPLES

The following example removes clock gating from all registers gated by the cell named *clk_gate_pipeline_reg_A* and removes the cell.

```
prompt> remove_clock_gates -gating_cell \
clk_gate_pipeline_reg_A
```

The following example removes clock gating from the gated registers named *pipeline_reg_A[0]* and *pipeline_reg_A[2]*. If the clock-gating cell that gates these registers does not drive any other gating cells, it is also removed.

```
prompt> remove_clock_gates \
-gated_registers {pipeline_reg_A[0] pipeline_reg_A[2]}
```

SEE ALSO

remove_clock_gating_check

Removes setup and hold checks from the specified clock gating cells.

SYNTAX

```
int remove_clock_gating_check
[-setup]
[-hold]
[-rise]
[-fall]
object_list
```

Data Types

object_list list

ARGUMENTS

-setup

Removes setup checks from the specified gating cells.

-hold

Removes hold checks from the specified gating cells.

-rise

Removes the clock gating constraint on the rising delays. If you do not specify either **-rise** or **-fall**, the default is to remove constraints on both rising and falling delays.

-fall

Removes the clock gating constraint on the falling delays. If you do not specify either **-rise** or **-fall**, the default is to remove constraints on both rising and falling delays.

If you omit the setup and hold arguments, by default both types of checks are removed.

object_list

Specifies a list of designs, cells, pins, or clock objects from which to remove the clock gating checks.

DESCRIPTION

The **remove_clock_gating_check** command removes clock gating checks that were added using the **set_clock_gating_check** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes setup and hold checks from the *CHIP1* design:

```
prompt> remove_clock_gating_check CHIP1
```

The following example removes only the setup checks on the clock gating inputs of the *CLK_GATE1* cell in the current design:

```
prompt> remove_clock_gating_check -setup CLK_GATE1
```

The following example removes only the fall hold checks on the clock gating inputs of the *CLK_GATE2* cell in the current design:

```
prompt> remove_clock_gating_check -fall -hold CLK_GATE2
```

SEE ALSO

```
create_clock(2)
current_design(2)
report_clock(2)
set_clock_gating_check(2)
```

remove_clock_groups

Removes specific exclusive or asynchronous clock groups from the current design.

SYNTAX

```
status remove_clock_groups
-logically_exclusive
| -asynchronous
| -physically_exclusive
name_list | -all
```

Data Types

name_list list

ARGUMENTS

-logically_exclusive

Specifies that groups set for logically exclusive clocks are to be removed. The **-logically_exclusive**, **-physically_exclusive** and **-asynchronous** options are mutually exclusive.

-asynchronous

Specifies that groups set for asynchronous clocks are to be removed. The **-exclusive** and **-asynchronous** options are mutually exclusive.

-physically_exclusive

Specifies that groups set for physically exclusive clocks are to be removed. The **-logically_exclusive**, **-physically_exclusive** and **-asynchronous** options are mutually exclusive.

name_list

Specifies a list of clock groups to be removed, which matches the groups in the given names. You should use the **set_clock_groups** command to predefine these names. Substitute the list you want for *name_list*. The *name_list* argument and **-all** option are mutually exclusive.

-all

Specifies to remove all groups set for exclusive or asynchronous clocks in the current design. The *name_list* argument and **-all** option are mutually exclusive.

DESCRIPTION

Removes specific exclusive or asynchronous clock groups from the current design. These clock groups are specified by the *name_list* from the current design. You must specify either **-logically_exclusive**, **-physically_exclusive** or **-asynchronous**. You must specify either *name_list* or **-all**.

To find the names for existing groups, use the **report_clock** command with the **-groups** option.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes logically exclusive clock groups named mux.

```
prompt> remove_clock_groups -logically_exclusive mux
```

The following example removes all asynchronous clock groups from the current design.

```
prompt> remove_clock_groups -asynchronous -all
```

SEE ALSO

`report_clock(2)`
`set_clock_groups(2)`

remove_clock_latency

Removes clock latency information from the specified objects.

SYNTAX

```
string remove_clock_latency
[-fall]
[-min]
[-max]
[-source]
[-early]
[-late]
object_list
[-rise]
```

Data Types

object_list list

ARGUMENTS

-fall

Specifies that the fall clock latency should be removed. By default, this is removed for both minimum and maximum clock latency.

-min

Specifies that the minimum clock latency should be removed. By default, this is removed for both rise and fall clock latency.

-max

Specifies that the maximum clock latency should be removed. By default, this is removed for both rise and fall clock latency.

-source

Specifies that clock source latency should be removed.

-early

Specifies that the late clock source latency should be removed. If this option is not specified, both early and late clock latencies are removed.

-late

Specifies that the late clock source latency should be removed. If this option is not specified, both early and late clock latencies are removed.

object_list

Provides a list of clocks, ports, or pins.

-rise

Specifies that the rise clock latency should be removed. By default, this is removed for both minimum and maximum clock latency.

DESCRIPTION

The **remove_clock_latency** command removes user-specified clock network or source latency information from specified objects. Clock network latency is the time it takes for a clock signal on the design to propagate from the clock definition point to a register clock pin. Clock source latency (also called insertion delay) is the time it takes for a clock signal to propagate from its actual ideal waveform origin point to the clock definition point in the design. Clock network and source latency information is set on objects using the **set_clock_latency** command. See the **set_clock_latency** man page for more information.

You can remove selected portions of the clock latency by specifying various such as **-rise**, **-fall**, **-min**, **-max**, **-late**, and **-early**.

To report clock network and source latency information, use the **report_clock** command with the **-skew** option.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes clock latency information from clock CLK1:

```
prompt> remove_clock_latency [get_clocks CLK1]
```

The following example removes clock source latency information from clock CLK1:

```
prompt> remove_clock_latency -source [get_clocks CLK1]
```

The following example removes only rise clock source latency information from clock CLK1:

```
prompt> remove_clock_latency -rise -source [get_clocks CLK1]
```

remove_clock_mesh

Removes the premesh tree, clock mesh or the postmesh tree routes and/or logical connections based on the options specified.

SYNTAX

```
status remove_clock_mesh
[-premesh]
[-clockmesh]
[-postmesh]
[-route_only]
[-clock_tree ]
```

ARGUMENTS

-premesh
Specifies the command to delete only the premesh part of the mesh tree.

-clockmesh
Specifies that the clockmesh needs to be removed.

-postmesh
Specifies the command to remove the post mesh tree.

-route_only
Specifies the command to remove only the routes and not touch the logical connectivity.

DESCRIPTION

The operation for various options specified are : For premesh : By default the pre-mesh tree including the last level mesh drivers will be removed along with pre-mesh routes. However, if the premesh option is given alongwith the other option - **route_only**, the logical pre-mesh tree will not be deleted but the pre-mesh routes till the input pins of the last level mesh drivers will be deleted. This **-route_only** may be useful when user wants to experiment with customized pre-mesh routes (like H/T/I) and with general routes We may have 2 conditions : 1) If there is no isolation buffer in the clock-mesh network, premesh tree means the tree starting from the clock root. The command **remove_clock_mesh** will remove the premesh tree starting from the root. 2) If there is an isolation buffer that implies that **adjust_premesh_connection** could separate out the mesh part from the macro pins. Also we need to be aware that **remove_clock_mesh** could be called after doing the whole flow which means optimization could have been called and which might have added buffers between the root and the isolation buffer and in the paths of those premesh macros. It is reasonable for **remove_clock_mesh** to do the following :- a) Remove premesh tree starting from the output of isolation buffer to the mesh b) Remove the buffers between the root and the isolation buffer's input c) Don't remove any logical objects on the macro paths and don't remove isolation buffer d) However, the routes, if any, will be deleted from the whole pre-mesh tree. (i.e., the routes of pre-isolation-buffer part, post isolation buffer part and the routes on the premesh macro paths). For clockmesh: If specified then all the routes (mesh straps and comb-

routes, if any) of the mesh net will be deleted. This implies the following things :- a) After clock-mesh deletion, the logical mesh net will remain multi-driven net unless otherwise the pre-mesh was already deleted. b) When user will form another set of straps (perhaps with different pitches etc.) after doing the clock-mesh deletion, **route_mesh_net** command must be run to make it completely routed

For postmesh: If this command is invoked with **-postmesh**, the command will expect that the pre-mesh tree and the mesh have already been deleted. In any case, this command will be just be deleting the routes, if any, between the ICG's and the flops. If the premesh and mesh have not been deleted already then the command will error out with a suitable message.

If this command is issued with no options, it will delete: (a) clock-mesh routes, (b) pre-mesh with routes, (c) post-mesh parts with routes in order.

In case the **-route_only** option is given then the command will give proper message saying that the intended usage is only for custom mesh structures.

EXAMPLE

The following command removes the clock mesh tree :

```
prompt> remove_clock_mesh -clock_tree clk1
```

SEE ALSO

```

adjust_premesh_connection(2)
add_clock_drivers(2)
compile_premesh_tree(2)
```

remove_clock_sense

Removes clock sense information from the specified pins.

SYNTAX

```
integer remove_clock_sense
[-all]
[-clocks clock_list]

```

Data Types

<i>clock_list</i>	list
<i>pins</i>	list

ARGUMENTS

-all

Removes all clock sense information in the current design. By default, this option is off.

-clocks *clock_list*

Specifies the list of clocks for which the clock sense information is removed. This option can remove only clock sense information that has been set by using the **set_clock_sense** command with the **-clocks** option. It does not remove clock sense settings from pins. By default, the clock sense information is removed for all clocks passing through the specified pins.

pins

Specifies the pins from which to remove clock sense information.

DESCRIPTION

This command removes user-specified clock sense (unateness) information from specified pins and clocks. To set clock sense information, use the **set_clock_sense** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes positive unateness defined on a pin named *XOR/Z* with respect to clock *CLK1*, but does not remove the negative unateness.

```
prompt> set_clock_sense -positive -clocks [get_clock CLK1] XOR/Z
prompt> set_clock_sense -negative XOR/Z
```

```
prompt> remove_clock_sense -clocks [get_clocks CLK1] XOR/Z
```

The following example removes all unateness information in the current design.

```
prompt> remove_clock_sense -all
```

SEE ALSO

`set_clock_sense(2)`

remove_clock_transition

Removes clock transition attributes on the specified clock objects.

SYNTAX

```
int remove_clock_transition  
clock_list
```

ARGUMENTS

`clock_list`
Specifies on which clocks the transition attributes must be removed.

DESCRIPTION

Removes the clock transition attributes on the specified clocks.

To list all clock transition values which have been set, use `report_clock -skew`.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes transition attributes on clock CLK.

```
prompt> remove_clock_transition CLK
```

The following example removes transition attributes on all clocks in the current design.

```
prompt> remove_clock_transition all_clocks()
```

SEE ALSO

`create_clock(2)`
`current_design(2)`
`report_clock(2)`
`reset_design(2)`
`set_clock_transition(2)`

remove_clock_tree

Removes buffers and inverters from the clock tree.

SYNTAX

```
status remove_clock_tree
[-clock_trees name_or_source_pin_list]
[-honor_dont_touch]
[-synopsys_only]
[-high_fanout_net net_or_pin_list]
```

Data Types

<i>name_or_source_pin_list</i>	list
<i>net_or_pin_list</i>	list

ARGUMENTS

-clock_trees *name_or_source_pin_list*

Removes only those clock trees whose names or root pins are listed in *name_or_source_pin_list*. Each element of *name_or_source_pin_list* must be either a clock tree name or a clock root (port or pin) shown in **report_clock**. By default, the command is applied to all currently defined clock trees.

-honor_dont_touch

Keeps buffers and inverters that have the **dont_touch** attribute. By default, this option is off.

-synopsys_only

Removes buffering for only those clock trees inserted by using the **compile_clock_tree** command. By default, this option is off.

-high_fanout_net *net_or_pin_list*

Removes a buffer tree for high fanout nets that were synthesized using **compile_clock_tree -high_fanout_net**. The nets or nets' driving pin must be specified in the *net_or_pin_list*.

DESCRIPTION

This command removes clock tree buffering and updates the design database with the results of the updated clock trees. The command removes only the clock tree buffering; the clock tree definition is maintained.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example reports an already inserted clock tree named CLK1, then removes all preexisting buffering.

```
prompt> report_clock_tree -clock_trees CLK1
prompt> remove_clock_tree -clock_trees CLK1
```

SEE ALSO

`compile_clock_tree(2)`
`report_clock_tree(2)`

remove_clock_tree_exceptions

Removes the specified clock tree exceptions, which were previously set with the **set_clock_tree_exceptions** command.

SYNTAX

```
status remove_clock_tree_exceptions
[-all]
[-float_pins float_pin_collection]
[-stop_pins stop_pin_collection]
[-non_stop_pins non_stop_pin_collection]
[-exclude_pins exclude_pin_collection]
[-dont_touch_subtrees dts_pin_collection]
[-dont_buffer_nets collection_or_list_of_nets]
[-dont_size_cells collection_or_list_of_cells]
[-size_only_cells collection_or_list_of_cells]
[-float_pin_logic_level]
[-preserve_hierarchy collection_of_pin_or_cells]
[-clocks object_list]
```

Data Types

<i>float_pin_collection</i>	collection
<i>stop_pin_collection</i>	collection
<i>non_stop_pin_collection</i>	collection
<i>exclude_pin_collection</i>	collection
<i>dts_pin_collection</i>	collection
<i>collection_or_list_of_nets</i>	collection
<i>collection_or_list_of_cells</i>	collection
<i>collection_of_pin_or_cells</i>	collection

ARGUMENTS

-all

Remove all the clock exceptions in the design.

-float_pins *float_pin_collection*

Specifies a list or collection of predefined float pins. When used with the **-float_pin_logic_level** option, only the logic-level value for the specified pins is reset to 0. Otherwise, both the phase delay and logic-level values for the specified pins are removed.

-stop_pins *stop_pin_collection*

Specifies the pins from which to remove the stop pin exception.

-non_stop_pins *non_stop_pin_collection*

Specifies the pins from which to remove the nonstop pin exception.

-exclude_pins *exclude_pin_collection*

Specifies the pins from which to remove the exclude exception.

```

-dont_touch_subtrees dts_pin_collection
    Specifies the pins from which to remove the dont_touch_subtree exception.

-dont_buffer_nets collection_or_list_of_nets
    Specifies the nets from which to remove the dont_buffer attribute.

-dont_size_cells collection_or_list_of_cells
    Specifies the cells from which to remove the dont_size attribute.

-size_only_cells collection_or_list_of_cells
    Specifies the cells from which to remove the size_only attribute.

-float_pin_logic_level
    Removes the logic-level value on the specified float pins. When used with the
    -float_pins option, the logic level on the specified pins is removed.
    Otherwise, the logic-level value is removed from all the pins in the design.

-preserve_hierarchy collection_of_pin_or_cells
    Specifies the pins or cells from which to remove the hierarchy preservation
    exception.

```

DESCRIPTION

This command removes the specified clock tree exceptions, which were previously set with the **set_clock_tree_exceptions**. You can remove the following exceptions: float pins (phase delay, logic level, or both), stop pins, exclude pins, dont_touch_subtree pins, dont_buffer nets, dont_size cells, and size_only cells.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example defines a float pin and then removes the definition.

```

prompt> set_clock_tree_exceptions -float_pins [get_pins RAM1/WE]
prompt> remove_clock_tree_exceptions -float_pins [get_pins RAM1/WE]

```

The following example defines a stop pin and then removes the definition.

```

prompt> set_clock_tree_exceptions -stop_pins [get_pins AND/B]
prompt> remove_clock_tree_exceptions -stop_pins [get_pins AND/B]

```

The following example removes all float pin logic-level exceptions:

```

prompt> remove_clock_tree_exceptions -float_pin_logic_level

```

The following example removes the float pin logic-level exception on the specified float pins:

```

prompt> remove_clock_tree_exceptions -float_pin_logic_level \

```

```
-float_pins {BUF1/A  BUF2/A  BUF3/A}
```

The following example defines an exclude pin and then removes the definition.

```
prompt> set_clock_tree_exceptions -exclude_pins [get_pins Reg1/CLK]
prompt> remove_clock_tree_exceptions -exclude_pins [get_pins Reg1/CLK]
```

The following example defines an cell for which boundary needs to be preserved and then removes the definition.

```
prompt> set_clock_tree_exceptions -preserve_hierarchy [get_cells Reg1]
prompt> remove_clock_tree_exceptions -preserve_hierarchy [get_cells Reg1]
```

SEE ALSO

```
set_clock_tree_exceptions(2)
set_clock_tree_options(2)
compile_clock_tree(2)
```

remove_clock_tree_options

Removes clock tree objects from database.

IMPORTANT NOTICE for IC Compiler

Note: This command is currently NOT SUPPORTED; Use the `reset_clock_tree_options` command instead. Ignore the rest of the document until this notice is removed.

SYNTAX

```
void remove_clock_tree_options
[-clock_trees name_or_source_pin_list]
```

Data Types

name_or_source_pin_list list

ARGUMENTS

-clock_trees *name_or_source_pin_list*

Removes only those clock trees whose names or root pins are listed in *name_or_source_pin_list*. Each element of *name_or_source_pin_list* can be either a user-assigned symbolic name or the name of the source (port or pin) of each clock tree. It must match one of the following:

- The *clock_tree_name* value set in the **-clock_tree_name** option of the `set_clock_tree_options` command used when creating the clock tree.
- The default clock tree name that is the full name of the clock tree root pin or port passed to the `set_clock_tree_options` command by specifying the *one_pin_col_spec* value of the **-root** option.
If you do not use the `remove_clock_tree_options` command with the **-clock_trees** option, the command is applied to all currently-defined clock-trees.

DESCRIPTION

This command deletes the database entry for the clock tree object predefined by the `set_clock_tree_options` command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This example creates and modifies a new clock tree structure named CLK1. The library units for the technology are in pico-seconds and femto-farads. It creates a clock tree with a source pin named U1/Z and then removes it.

```
prompt> set_clock_tree_options -clock_tree_name CLK1\  
-root [get_pins U1/Z]  
prompt> remove_clock_tree_options -clock_trees CLK1
```

SEE ALSO

[set_clock_tree_options \(2\)](#)

remove_clock_uncertainty

Removes clock uncertainty information previously set by the **set_clock_uncertainty** command.

SYNTAX

```
string remove_clock_uncertainty
[object_list
 | -from from_clock
 | -rise_from rise_from_clock
 | -fall_from fall_from_clock
-to to_clock
 | -rise_to rise_to_clock
 | -fall_to fall_to_clock]
[-rise]
[-fall]
[-setup]
[-hold]
```

Data Types

<i>object_list</i>	list
<i>from_clock</i>	list
<i>rise_from_clock</i>	list
<i>fall_from_clock</i>	list
<i>to_clock</i>	list
<i>rise_to_clock</i>	list
<i>fall_to_clock</i>	list

ARGUMENTS

object_list
Specifies a list of clocks, ports, or pins from which uncertainty information is to be removed. By default, uncertainty information is removed from all objects in the current design. Use either the pair of **-from/-rise_from/-fall_from** and **-to/-rise_to/-fall_to** options or the *object_list* option. Do not specify both, because they are mutually exclusive.

-from *from_clock*
Specifies the source and destination clocks for interclock uncertainty. Specify either the pair of **-from/-rise_from/-fall_from** and **-to/-rise_to/-fall_to**, or *object_list*. Do not specify both.

-rise_from *rise_from_clock*
Specifies the source and destination clocks, but indicates that *uncertainty* applies only to the rising edge of the source clock. Use only one of the **-from**, **-rise_from**, or **-fall_from** options.

-fall_from *fall_from_clock*
Specifies the source and destination clocks, but indicates that *uncertainty* applies only to the falling edge of the source clock. Use only one of the **-from**, **-rise_from**, or **-fall_from** options.

-to *to_clock*
 Specifies the destination clocks for interclock uncertainty. Specify either the pair of **-from/-rise_from/-fall_from** and **-to/-rise_to/-fall_to**, or *object_list*. Do not specify both.

-rise_to *rise_to_clock*
 Specifies the destination clocks for interclock uncertainty, but indicates that *uncertainty* applies only to the rising edge of the destination clock. Use only one of the **-to**, **-rise_to**, or **-fall_to** options.

-fall_to *fall_to_clock*
 Specifies the destination clocks for interclock uncertainty, but indicates that *uncertainty* applies only to the falling edge of the destination clock. Use only one of the **-to**, **-rise_to**, or **-fall_to** options.

-rise
 Specifies that uncertainty is to be removed for only the rising clock edge. By default, uncertainty is removed for both rising and falling clock edges. This option is valid only for interclock uncertainty, and is now obsolete. Unless you need this option for backward-compatibility, use **-rise_to** instead.

-fall
 Specifies that uncertainty is to be removed for only the falling clock edge. By default, uncertainty is removed for both rising and falling clock edges. This option is valid only for interclock uncertainty, and is now obsolete. Unless you need this option for backward-compatibility, use **-fall_to** instead.

-setup
 Specifies that only setup check uncertainty is to be removed. By default, both setup and hold check uncertainties are removed.

-hold
 Specifies that only hold check uncertainty is to be removed. By default, both setup and hold check uncertainties are removed.

DESCRIPTION

Removes clock uncertainty information previously set by the **set_clock_uncertainty** command from clocks, ports, or pin or between specified clocks. If the command is issued without options, all clock uncertainty information is removed from the current design. To display clock uncertainty information, use the **report_clock** command with the **-skew** option.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes uncertainty information from a clock named *CLK* and a pin named *clk_buf/Z*.

```
prompt> remove_clock_uncertainty [get_clocks CLK]
prompt> remove_clock_uncertainty [get_pins clk_buf/z]
```

The following example removes interclock uncertainties between the *PHI1* and *PHI2* clock domains:

```
prompt> remove_clock_uncertainty -from PHI1 -to PHI1
prompt> remove_clock_uncertainty -from PHI2 -to PHI2
prompt> remove_clock_uncertainty -from PHI1 -to PHI2
prompt> remove_clock_uncertainty -from PHI2 -to PHI1
```

SEE ALSO

```
all_clocks(2)
create_clock(2)
report_clock(2)
set_clock_latency(2)
set_clock_transition(2)
set_clock_uncertainty(2)
```

remove_congestion_options

Removes congestion options from the current design.

SYNTAX

```
int remove_congestion_options
[-all] id_list
```

Data Types

id_list list

ARGUMENTS

-all
Specifies to remove all congestion options from the current design.

id_list
Indicates to remove congestion options with the specified ids.

DESCRIPTION

The **remove_congestion_options** command removes the congestion options from the current design. If the **-all** option is specified, all congestion options are removed from the design. If a list of ids is provided, the congestion options with the specified ids are removed. The id is displayed every time a regional congestion option is created. Or, it can be viewed by using the **report_congestion_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all congestion options.

```
prompt> remove_congestion_options -all
```

SEE ALSO

report_congestion(2)
report_congestion_options(2)
set_congestion_options(2)

remove_cts_scenario

Removes the current CTS scenario setting. This command doesn't remove the scenario itself, it only removes the CTS scenario setting.

SYNTAX

Boolean **remove_cts_scenario**

ARGUMENTS

The **remove_cts_scenario** command has no arguments.

DESCRIPTION

Removes the CTS scenario setting on currently defined cts scenario. in MCMM flow, compile_clock_tree, optimize_clock_tree and balance_inter_clock_delay will work on the CTS scenario (if defined), or on current scenario if the CTS scenario is not defined. This command always returns a "true" value.

Multicorner-Multimode Support

This command uses information from the clock tree synthesis scenario.

EXAMPLES

The following example uses **remove_cts_scenario** to remove cts scenario.

```
prompt> create_scenario MODE1
prompt> set_cts_scenario MODE1
MODE1
prompt> get_cts_scenario
MODE1
prompt>remove_cts_scenario
1
prompt>get_cts_scenario

prompt>
```

SEE ALSO

`balance_inter_clock_delay(2)`
`clock_opt(2)`
`compile_clock_tree(2)`
`get_cts_scenario(2)`
`optimize_clock_tree(2)`
`set_cts_scenario(2)`

remove_dangling_wires

Removes dangling wires and vias on specified nets, except for power and ground nets and those with short or open violations.

SYNTAX

```
integer remove_dangling_wires
[-nets {collection_of_nets}]
[-route_types {list_of_route_types}]
[-layers {collection_of_layers}]
[-no_rerun_drc]
```

Data Types

<i>collection_of_nets</i>	collection
<i>list_of_route_types</i>	list
<i>collection_of_layers</i>	collection

ARGUMENTS

-nets {collection_of_nets}

Specifies the target nets with dangling wires or vias to be removed. The command removes them on target nets except power and ground nets.

-route_types {list_of_route_types}

Specifies a list of the target route types of nets. The valid values for route types are **user_enter**, **signal_route_detail**, **clk**. These route types are defined as follows:

user_enter is for signal user enter (signal net).

signal_route_detail is for signal detail route (signal net)

clk is for clock strap or clock user enter (clock net)

all is for all route types

The default is **all**.

The **-route_types** option cannot support all of the route types defined in Milkyway database due to the router limitation.

-layers {collection_of_layers}

Specifies the target layers of the dangling wires/vias to be removed. The default is **all**.

-no_rerun_drc

Suppresses the running of design rule checking (verify_route) before starting the removal of dangling wires and vias. By default, the command runs DRC.

DESCRIPTION

This command removes dangling wires and vias on user-specified nets without changing topologies and connections. Only antenna (dangling) wires and vias are trimmed, and the command does not touch terminals. The removal excludes from the target nets all power and ground nets and nets having short or open violations

NOTES

This command eliminates dangling wires and vias on the types of detail route and user enter for signal nets and the types of user enter and strap for clock nets. If the command target nets are clock nets and if there are dangling wires or vias on clock straps or clock user enter, then the first dangling wire or via can be removed, but consecutive removing across a via is not guaranteed.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the command for the clock net ck1 with user enter route type to remove dangling wires on layers metal6 and metal7, and floating vias on layer via6.

```
prompt> remove_dangling_wires \
-nets {ck1} -route_types {clk} \
-layers {metal6 metal7 via6} \
-no_rerun_drc
```

SEE ALSO

`verify_route(2)`

remove_data_check

Removes specified data-to-data checks previously set by `set_data_check`.

SYNTAX

```
string remove_data_check
  -from from_object
    | -rise_from from_object
    | -fall_from from_object
  -to to_object
    | -rise_to to_object
    | -fall_to to_object
  [-setup | -hold]
  [-clock clock]
```

Data Types

<i>from_object</i>	collection
<i>to_object</i>	collection

ARGUMENTS

-from *from_object*
Specifies a pin or port in the current design as the related pin of the data-to-data check to be removed. Both rising and falling checks are removed. You must specify one of **-from**, **-rise_from**, or **-fall_from**.

-rise_from *from_object*
Similar to the **-from** option, but applies to only rising delays at the related pin. You must specify one of **-from**, **-rise_from**, or **-fall_from**.

-fall_from *from_object*
Similar to the **-from** option, but applies to only falling delays at the related pin. You must specify one of **-from**, **-rise_from**, or **-fall_from**.

-to *to_object*
Specifies a pin or port in the current design as the constrained pin of the data-to-data check to be created. Both rising and falling checks are removed. You must specify one of **-to**, **-rise_to**, or **-fall_to**.

-rise_to *to_object*
Similar to the **-to** option, but applies to only rising delays at the constrained pin. You must specify one of **-to**, **-rise_to**, or **-fall_to**.

-fall_to *to_object*
Similar to the **-to** option, but applies to only falling delays at the constrained pin. You must specify one of **-to**, **-rise_to**, or **-fall_to**.

-setup
Indicates that only the setup data check is to be removed. If neither **-setup** nor **-hold** is specified, both setup and hold checks are removed.

-hold
Indicates that only the hold data check is to be removed. If neither **-setup** nor **-hold** is specified, both setup and hold checks are removed.

-clock clock
Indicates that the data check for the specified clock at the related pin is to be removed. This option applies only if a previous **set_data_check** command used the **-clock** option to specify the same clock; otherwise, this option is ignored.

DESCRIPTION

The **remove_data_check** command specifies data-to-data check(s) to be removed between the from object and to object for the specified options. These checks were previously set using the **set_data_check** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes a data-to-data check from and1/B to and1/A with respect to the rising edge of signals at and1/B. Both setup and hold checks are removed.

```
prompt> remove_data_check -rise_from and1/B -to and1/A
```

The following example removes setup data-to-data check between and1/B to and1/A with respect to the rising edge of signals at and1/B, coming from startpoints triggered with clock CK1, falling edge of signals at and1/A.

```
prompt> remove_data_check -rise_from and1/B \
-fall_to and1/A -setup -clock [get_clock CK1]
```

SEE ALSO

`report_timing(2)`
`set_data_check(2)`
`update_timing(2)`
`timing_enable_multiple_clocks_per_reg(3)`

remove_design

Removes a list of designs or libraries from memory.

SYNTAX

```
status remove_design  
[design_list | -designs | -all]  
[-hierarchy] [-quiet]
```

Data Types

design_list list

ARGUMENTS

design_list
Specifies a list of designs or libraries to removed. The default is the current design. Cannot be used with **-designs** or **-all**. The design to remove is either with an absolute path or without. To know the absolute path of designs, use the list -files.

-designs
Indicates that all designs in memory are to be removed. Cannot be used with *design_list* or **-all**.

-all
Indicates to remove all designs and libraries in memory. Cannot be used with *design_list* or **-designs**.

-hierarchy
Indicates to remove all designs within the hierarchy of the designs in the *design_list* or in the current design. The default is not to remove any subdesigns.

-quiet
Turns off verbose mode that prints out messages showing the names of the designs or libraries that are being removed.

DESCRIPTION

Removes a list of designs or libraries from memory. If you do not specify any arguments, the current design is removed. When a design or library is removed, the memory it occupies is freed.

NOTE: Memory is freed to be reused by this same process. However, memory is not returned to the operating system until you exit the tool.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

remove_design

1416

EXAMPLES

The following example removes the current design.

```
prompt> current_design TEST
Current design is now 'TEST'

prompt> remove_design
Removing design 'TEST'
```

The following example removes a specified design and all subdesigns in the hierarchy.

```
prompt> remove_design -hier TEST2

Removing design 'TEST2'
Removing design 'ADDER'
Removing design 'MUX8'
Removing design 'ND17'
```

The following example removes a specified design RIGHT in file TOP.ddc:

```
prompt> remove_design {"/remote/qe5/bill/designs/TOP.ddc:RIGHT"}

Removing design 'RIGHT'
```

The following example removes all design and library objects from memory.

```
prompt> remove_design -all
Removing design 'A'
Removing design 'B'
Removing library 'test_lib'
```

SEE ALSO

remove_diode

deletes the diode cells

SYNTAX

```
integer remove_diode
[-cells diode_cell_name]
-nets collection_of_nets
[-all_clock_net]
[-dangling_wires]
```

Data Types

<i>diode_cell_name</i>	list
<i>collection_of_nets</i>	list

ARGUMENTS

```
-cells diode_cell_name
      Specify one or more diode cells to delete. Default : Search the design library
      and all its reference libraries for all the diode cells to delete. A diode
      cell is a cell that has at least one diode port.

-nets collection_of_nets
      specify either one net or a pattern to match the names of multiple nets of
      the diode ports to be disconnected

-all_clock_net
      disconnect all diode ports on all clock nets. If this option is selected,
      then the specified nets will be ignored.

-dangling_wires
      After deleting the diode cell instances, the wires that were connected to the
      diode ports, became dangling. This can be cleaned up by setting this option.
      Note that it removes all dangling wires, even those that existed before
      running this command.
```

DESCRIPTION

Prerequisites : The cell must be opened with write permission.

Helps you delete the diode cells inserted for fixing antenna violations. It deletes the diode cell given by the name of the diode cell and the net names. It first disconnects all the diode ports on all the given nets. Then it delete the diode cells that are fully disconnected (that is, no connected port (except power and ground) and no connected diode port). The exact behavior of the command is given in the steps below:

- + Disconnect all the diode port instances in all the cell instances of the given diode cells on all the given nets.

- + Delete the cell instances that are fully disconnected of the given diode cells. A fully disconnected cell instance contains no connected port (except power and ground) and no connected diode port.
- + Delete all dangling wires, if the option is set.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example delete diode cells M1B2H and M1A3K, and disconnect net NET_INV05 from cells. Also, remove any possible dangling wires after clear up cells and nets.

```
prompt> remove_diode -cells {M1B2H M1A3K} -nets NET_INV05 -dangling_wires
```

SEE ALSO

remove_disable_clock_gating_check

For specified cells and pins, restores clock gating checks previously disabled by the `set_disable_clock_gating_check` command.

SYNTAX

```
string remove_disable_clock_gating_check
object_list
```

Data Types

object_list list

ARGUMENTS

object_list
Specifies a list of cells and pins for which previously-disabled clock gating checks are to be restored.

DESCRIPTION

For specified cells and pins, restores clock gating checks previously disabled by the `set_disable_clock_gating_check` command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example restores disabled clock gating checks for the object named *an1*.

```
prompt> remove_disable_clock_gating_check an1/A
```

The following example restores all disabled gating checks on the cells named *U1* or *U2*.

```
prompt> remove_disable_clock_gating_check U1/or2
```

SEE ALSO

`set_disable_clock_gating_check(2)`

remove_disable_timing

Enable previously user-disabled timing arcs in the current design. It is an equivalent to set_disable_timing -restore.

SYNTAX

```
int remove_disable_timing  
object_list  
[-from from_pin_name -to to_pin_name] [-all_loop_breaking]
```

Data Types

object_list	list
from_pin_name	string
to_pin_name	string

ARGUMENTS

object_list
Specifies a list of cells, pins, ports, library pins, or library cells that are to be enabled. The cells or the cells of pins are no longer size only if size only were not set by the user.

-from from_pin_name
Specifies that arcs only from this pin on the specified cell are to be enabled. The object_list must contain only cells if **-from** and **-to** are specified.

-to to_pin_name
Specifies that arcs only to this pin on the specified cell are to be enabled. The object_list must contain only cells if **-from** and **-to** are specified.

-all_loop_breaking
Re-enable all the stored loop-breaking timing arcs. Only applies to the entire design.

DESCRIPTION

The **remove_disable_timing** command enables timing through the specified cells, pins, or ports in the current design.

Any cell, pin, or port in the current design or its subdesigns can be disabled and thus re-enabled. Cells at lower levels in the design hierarchy are specified as *instance1/instance2/cell_name*. Pins at lower levels in the design hierarchy are specified as *instance1/instance2/cell_name/pin_name*. Ports at lower levels in the design hierarchy are specified as *instance1/instance2/cell_name/port_name*.

Library pins and library cells can also be disabled and re-enabled.

Note: For subdesigns in the hierarchy, you must specify instance names instead of design names.

In disabling, when the timing through a cell is disabled, only those cell arcs that lead to the output pins of the cell are disabled. When the timing through a pin or port is disabled, only those cell arcs that lead to or from that pin or port are disabled. The `remove_disable_timing` command has a reverse effect.

When the `-from` and `-to` pins are specified, all arcs between these pins on the cell are enabled.

Use `report_lib -timing_arcs` to list the timing arcs for a library cell, and `report_design` to list the disabled arcs in the current design so as to check the enabling effect of the `remove_disable_timing` command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

In the following example, all timing arcs between pins 'A' and 'Z' on cell U1/U1 in the current design are enabled.

```
prompt> remove_disable_timing U1/U1 -from A -to Z
```

In the following example, all timing arcs between pins 'D' and 'Q' on cell FD1 in the library 'my_lib' are enabled. This command enables arcs on a library cell; therefore, all instances of that library cell are affected in any design linked to the same library.

```
prompt> remove_disable_timing my_lib/FD1 -from D -to Q
```

SEE ALSO

```
current_design(2)  
remove_attribute(2)  
report_lib(2)  
reset_design(2)  
set_disable_timing(2)
```

remove_distributed_hosts

Remove all the hosts added to the distributed hosts list.

SYNTAX

```
int remove_distributed_hosts
```

ARGUMENTS

The **remove_distributed_hosts** command has no arguments.

DESCRIPTION

The **remove_distributed_hosts** command removes all the hosts that were added to the list of distributed hosts by the **add_distributed_hosts** command. The command will only remove all the hosts provided none of the slave processes have been launched. If any of the slave processes have been launched then the command will fail.

EXAMPLES

In the following example, the following distributed hosts are added platinum1, two 64 bit hosts platinum2, four 32 bit hosts 1 lsf queue, four 64 bit hosts All entries are then removed.

```
prompt> add_distributed_hosts -farm now -num_of_hosts 2 platinum1
1
prompt> add_distributed_hosts -farm now -num_of_hosts 4 platinum2 -32bit
1
prompt> add_distributed_hosts -farm lsf -submission_script "/bin/
lsf_stub"
-options {-R "tmp>300" -q} -num_of_hosts 4
1
prompt> remove_distributed_hosts
1
```

SEE ALSO

[add_distributed_hosts\(2\)](#)

remove_distributed_route

Terminates a job.

SYNTAX

```
integer remove_distributed_route
-job jobId
```

Data Types

jobId integer

ARGUMENTS

```
-job jobId
      Specified a job ID.
```

DESCRIPTION

Passes in a job ID, and the program terminates the process that runs the specified job.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example is to kill the process of a job with ID 100.

```
prompt> remove_distributed_route -job 100
```

SEE ALSO

```
set_distributed_route(2)
report_distributed_route(2)
close_distributed_route(2)
```

remove_dont_touch_placement

Removes the restriction of fixed placement from a leaf cell and/or cluster.

SYNTAX

```
status remove_dont_touch_placement  
object_list
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of objects, each of which is a leaf cell or a cluster, from which the restriction will be removed.

DESCRIPTION

The **remove_dont_touch_placement** command removes the restriction for fixed placement from a leaf cell and/or a cluster. It can remove FIXED PLACEMENT, defined in the PDEF file for a cell, or the restriction set by the **set_dont_touch_placement** command on a cell.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to remove the restriction from the instance INST_1.

```
prompt> remove_dont_touch_placement INST_1
```

SEE ALSO

```
create_placement(2)  
set_cell_location(2)  
set_dont_touch_placement(2)
```

remove_dp_int_round

Remove the rounding attribute from datapath output nets.

SYNTAX

```
int remove_dp_int_round
nets
```

Data Types

nets list

ARGUMENTS

nets

List of nets that the rounding attributes will be removed from.

DESCRIPTION

This command removes the external and internal rounding attributes that are set by **set_dp_int_round** command.

Note: When a design is compiled and is been internally rounded. Constant propagation may happen in the design. If you remove the internal rounding attribute and do compile again. The final netlist may fail Formality check as constant propagation may disconnect some nets. So it is not suggested to remove the internal rounding attribute and do incremental compile.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the external rounding value on net z1*:

```
prompt> remove_dp_int_round [find net z1*] 7 5
```

SEE ALSO

`set_dp_int_round(2)`

remove_drc_error

Remove one or more errors from the error view.

SYNTAX

```
status remove_drc_error
-drc_error drc_error
[-error_view mw_error_view]
drc_error
```

Data Types

<i>drc_error</i>	list or collection
<i>mw_error_view</i>	list or collection

ARGUMENTS

```
-drc_error drc_error
The error objects to remove. This argument is required.

-error_view mw_error_view
The error view from which to remove the error records. If omitted, the error
records are removed from the current top-level design cell. Specifying more
than one error view causes an error.
```

DESCRIPTION

This command removes error records from the error view.

EXAMPLES

The following example creates an error record of the type "Short" in the current top-level design, then removes it:

```
prompt> set errId [create_drc_error -type "Short"]
{1280}
prompt> remove_drc_error -drc_error $errId
1
```

SEE ALSO

```
create_drc_error(2)
create_open_drc_error(2)
create_open_locator_drc_error(2)
create_short_drc_error(2)
create_spacing_drc_error(2)
get_drc_errors(2)
```

remove_driving_cell

Removes driving cell attributes from the specified input or inout ports of the current design.

SYNTAX

```
int remove_driving_cell
[port_list]
```

Data Types

port_list list

ARGUMENTS

port_list

Specifies a list of names of input or inout ports in the current design, from which the driving cell attributes are to be removed. If more than one port is specified, they must be enclosed in either quotes or braces ({}).

DESCRIPTION

Removes attributes associated with an external driving cell from the specified input or inout ports in the current design.

To view drive information on ports, use **report_port -drive**.

The **characterize** command automatically sets driving cell attributes on subdesign ports based on their context in the entire design.

This command has the same functionality as **reset_design** in removing the attributes on the ports.

Note: **remove_driving_cell** removes any corresponding rise or fall drive resistance attributes (from **set_drive**) from the specified ports. If possible, always use **remove_driving_cell** instead of **set_drive**, because **remove_driving_cell** is more accurate. This command replaces **set_driving_cell -none** in the 1999.05 version of Design Compiler.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes driving cell attributes from all input and inout ports.

```
prompt> remove_driving_cell all_inputs()
```

SEE ALSO

`all_inputs(2)`
`characterize(2)`
`current_design(2)`
`report_port(2)`
`reset_design(2)`
`set_drive(2)`
`set_driving_cell(2)`

remove_edit_groups

Removes a list of edit groups.

SYNTAX

```
collection remove_edit_groups
[-all]
[-quiet]
[objects]
```

ARGUMENTS

-all

Specifies that all edit groups are to be removed.

-quiet

Specifies that error and warning messages should be suppressed.

objects

Specifies the edit groups to be removed. The **objectsfp** and the **-all** options are mutually exclusive.

DESCRIPTION

Removes a list of edit groups from the current design. If the command is executed successfully, the tool returns a collection of undeleted objects and children of deleted edit groups. Any object specified in the **objects** option which was not deleted either due to database failure, or because it was not an edit group is added to this collections. The children of any successfully deleted edit groups are also added. The return collection allows the user to chain edit group operations together. See examples below.

EXAMPLES

The following example removes the edit groups from the currently selected objects.

```
prompt> remove_edit_groups [get_selection]
```

The following example creates a new edit group from the currently selected objects which may already contain existing edit groups.

```
prompt> create_edit_group [remove_edit_groups [get_selection]]
```

SEE ALSO

`remove_objects(2)`

remove_filler_withViolation

Deletes filler cells that have routing violations

SYNTAX

```
integer remove_filler_with_violation  
-name cell_name
```

Data Types

cell_name list

ARGUMENTS

```
-name cell_name  
      The pattern of the names of the cell instances
```

DESCRIPTION

Deletes all the filler cells that have routing design rule violations. Filler cells are standard cells without any connections to signal nets. The command is useful when filler cells are added after signal routing.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all filler cells with the prefix "xofiller" that have routing violations.

```
prompt> remove_filler_with_violation -name "xofiller.*"
```

SEE ALSO

`insert_stdcell_filler(2)`

remove_flip_chip_route

Removes the specified flip-chip wires and contacts.

SYNTAX

```
status remove_flip_chip_route
[-nets collection_of_nets
 | -nets_in_file nets_file]
[-width width]
[-contact]
```

Data Types

<i>collection_of_nets</i>	collection
<i>nets_file</i>	string
<i>width</i>	float

DATA TYPES

<i>collection_of_nets</i>	collection
<i>nets_file</i>	string
<i>width</i>	float

ARGUMENTS:

-nets collection_of_nets

Specifies the flip-chip wires to remove.

This option and the **-nets_in_file** option are mutually exclusive; you can specify only one. If you do not specify either option, all flip-chip nets are removed.

-nets_in_file nets_file

Specifies the name of the file that contains the flip-chip wires to remove.

This option and the **-nets** option are mutually exclusive; you can specify only one. If you do not specify either option, all flip-chip wires are removed.

-width width

Removes only the flip-chip wires with the specified width. The unit for the width value is the unit specified in the technology file.

-contact

Removes the contacts of the specified wires, as well as the wires. By default, the wires are removed but the contacts are not.

DESCRIPTION

This command removes the specified flip-chip wires and contacts.

EXAMPLES

The following command removes all flip-chip wires.

```
prompt> remove_flip_chip_route
```

The following command removes all flip-chip wires and contacts.

```
prompt> remove_flip_chip_route -contact
```

The following command removes all flip-chip wires with a width of 10 user units.

```
prompt> remove_flip_chip_route -width 10
```

SEE ALSO

`set_route_flip_chip_options(2)`
`route_flip_chip(2)`
`create_stack_via_on_pad_pin(2)`
`write_flip_chip_nets(2)`
`push_flip_chip_route(2)`
`display_flip_chip_route_flylines(2)`
`optimize_flip_chip_route(2)`

remove_fp_block_shielding

Removes signal shielding (route blockages) created by `create_fp_block_shielding`.

SYNTAX

```
status remove_fp_block_shielding
[-inside_boundary]
[-outside_boundary]
[-side_list {left | right | top | bottom}]
[-metal_layers layer_list]
[objects]
```

ARGUMENTS

-inside_boundary

Specifies that the command will remove shielding on the inside of plan group(s) and/or soft macro(s). If this option and the `-outside_boundary` option are not specified, then shielding is removed on both the interior and exterior sides of the plan group(s) and/or soft macro(s).

-outside_boundary

Specifies that the command will remove shielding on the outside of the plan group(s) and/or soft macro(s). If this option and the `-inside_boundary` option are not specified, then shielding is removed on both the interior and exterior sides of the plan group(s) and/or soft macro(s).

-side_list {left | right | top | bottom}

Indicates the side(s) on which the command will remove shielding rectangles. If this option is not specified, then shielding is removed on all sides of the plan group(s) and/or soft macro(s).

-metal_layers layer_list

A layer object collection that specifies the metal layer(s) on which shielding will be removed. If no layers are specified with this option, then the command removes shielding from all layers.

objects

Collection of plan group(s) and/or soft macro(s) from which to remove route blockages (shielding). If omitted, then all plan groups and all soft macros will be processed.

DESCRIPTION

This command removes signal shielding (route blockages) created by `create_fp_block_shielding`. A list of plan groups and/or soft macros can be specified to be processed. If none are specified, then the command removes shielding from all plan groups and soft macros that contain existing shielding rectangles.

The command can be flagged to remove shielding on the inside and/or outside of a plan group/soft macro.

The command accepts a list of sides that indicates the sides on which shielding should be removed. If no side is specified, the command removes shielding on all sides.

The metal layers where shielding will be removed can be specified. If no layers are specified, then the command will remove shielding on each metal layer. The argument to this option is a collection of layer objects returned by the get_layer command (example [get_layer {metal1 metal2}]). Layer names or mask names are acceptable. Use of [get_layer {layer_list}] is optional... the following option is acceptable: - metal_layers {metal1 metal2 metal3}. Be sure the names are either legal layer names or legal mask names.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes inside shielding on left side of selected plan groups and soft macros:

```
> remove_fp_block_shielding -inside_boundary -side_list left  
[get_cells {large_macro small_macro medium_plan_group}]  
> remove_fp_block_shielding -metal_layers [get_layer {metal1 metal2 metal3}] -  
side_list {left right}  
[get_selection]
```

SEE ALSO

`create_fp_block_shielding(2)`

remove_fp_feedthroughs

Removes feedthrough ports and nets that exist within the design.

SYNTAX

```
status remove_fp_feedthroughs
[-include {buffered original}]
[-nets object_list]
[-blocks object_list]
[-voltage_areas object_list]
```

Data Types

object_list collection

ARGUMENTS

-include {buffered original}

This option indicates whether the user wants to remove buffered, or original, or both buffered and original feedthroughs in addition to the default. The supported values are described below.

buffered

When **-include buffered** is specified, the command removes buffered feedthrough ports that are determined to be "added" in addition to unbuffered feedthroughs, and removes the connections to these ports. The tool will also remove these feedthrough buffers and inverting buffers.

The default behavior of **remove_fp_feedthroughs** is to preserve the buffered feedthroughs and their connections.

original

When **-include original** is specified, the command removes feedthrough ports that are determined to be "original" in addition to "added" ports. If you specify this option, the tool removes these feedthrough ports and the connections to these ports at the top level.

The default behavior of **remove_fp_feedthroughs** is to preserve "original" ports and their top-level connections.

-nets object_list

Specifies the flat nets from which to remove feedthrough ports. If you do not specify this option, all flat nets are processed for feedthrough removal.

-blocks object_list

Specifies the plan groups and soft macros from which to remove route feedthrough ports and nets.

If you do not specify this option, all plan groups and all soft macros are processed.

```
-voltage_areas object_list
    Specifies the voltage areas from which to remove route feedthrough ports and
    nets.
    If you do not specify this option, all voltage areas are processed.
```

DESCRIPTION

This command removes feedthrough ports and nets that exist within the design. This command, when specified with no arguments, removes all "added" feedthrough nets and ports ("original" nets and ports on blocks voltage areas are preserved by default) from all nets on all blocks (including both plan group blocks and soft macro blocks) and all voltage areas. The command determines by examination which ports and nets are feedthrough nets. If you want to apply the command to a subset of nets, use the **-nets** option to specify a collection of flat nets to be processed. Similarly, if you want to apply the command to certain blocks or voltage areas, use the f-blocks or f-voltage_areass options to specify a collection of plan group and soft macro blocks or voltage areas to be processed.

The command accepts the **-include original** option to instruct the command to remove nets and ports that are deemed to be "original" in addition to "added" nets and ports. The "original" is defined as all ports on blocks and voltage areas that are determined to be feedthrough ports, but are not determined to be "added" ports. By default, these "original" nets and ports are not removed. If you specify this option, the tool removes original feedthrough ports and their connections to the top-level nets.

When **-include buffered** option is specified, the tool can detect the feedthroughs with buffers inserted, remove the "added" feedthrough ports and delete the inserted buffers and inverting buffers where the buffered feedthroughs are removed.

This command also accepts the **-include {buffered original}** option to allow users to remove both buffered and "original" feedthrough nets and ports in addition to the default.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes feedthrough nets and ports on all nets, blocks and voltage areas:

```
prompt> remove_fp_feedthroughs
```

The following example removes feedthrough nets and ports on all specified nets and blocks:

```
prompt> remove_fp_feedthroughs -nets {[get_selection]} \
-blocks {[get_cells "BlockA BlockB"]}
```

The following example removes feedthrough nets in the selection on at least one of

PGA, PGb, or VAc:

```
prompt> remove_fp_feedthroughs -nets {[get_selection]} \
    -blocks {[get_plan_groups {PGA PGb}]} \
    -voltage_areas [get_voltage_areas VAc]
```

The following example removes feedthrough nets and ports on all specified voltage areas:

```
prompt> remove_fp_feedthroughs \
    -voltage_areas {[get_voltage_areas "voltage_area_0"]}
```

The following example removes feedthrough nets and ports on all nets, blocks and voltage areas and removes the original feedthrough ports:

```
prompt> remove_fp_feedthroughs -include original
```

The following example removes feedthrough nets and ports on all nets, blocks and voltage areas. In addition, it removes the original feedthrough ports, removes the added buffered feedthrough ports, and deletes the buffers where buffered feedthroughs have been removed:

```
prompt> remove_fp_feedthroughs -include {buffered original}
```

SEE ALSO

`analyze_fp_routing(2)`

remove_fp_pin_constraints

Resets the pin assignment constraints for the specified soft macros or plan groups to the default values.

SYNTAX

```
status remove_fp_pin_constraints
[-block_level]
[blocks]
```

Data Types

blocks collection

ARGUMENTS

-block_level

Resets the block-level pin assignment constraints on the specified soft macro rather than the top-level pin assignment constraints on the top-level design. By default, the top-level pin assignment constraints for the specified soft macros are reset on the top-level design.

blocks

Specifies the soft macros and plan groups on which to reset the pin assignment constraints. If you do not specify this argument, the pin assignment constraints are reset on all soft macros and plan groups.

DESCRIPTION

This command resets the pin assignment constraints for the specified soft macros and plan groups to the default values. You specify the pin assignment constraints with the **set_fp_pin_constraints** command. The **place_fp_pins** and **analyze_fp_routing** commands use these constraints when creating pins.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example resets the top-level pin assignment constraints for all soft macros and plan groups in the current design to the default values.

```
prompt> remove_fp_pin_constraints
```

SEE ALSO

analyze_fp_routing(2)
place_fp_pins(2)

```
set_fp_pin_constraints(2)
```

```
remove_fp_pin_constraints  
1440
```

remove_fp_pin_overlaps

Removes overlaps between all pins on the specified soft macros and the specified top-level or soft macro pins.

SYNTAX

```
status remove_fp_pin_overlaps
[-cells collection]
[-pins collection]
```

ARGUMENTS

```
-cells collection
      collection of soft macros to remove pin overlaps for

-pins collection
      collection of pins to remove overlaps for
```

DESCRIPTION

Removes overlaps between all pins on the specified soft macros and/or specified top level or soft macro pins.

If no cells or pins are specified then overlaps are removed from all top level and all soft macro pins.

See the example below if overlap removal is desired only for top-level pins (i.e. terminals).

If overlap removal fails (because there are too few wiretracks available or pin placement is overconstrained) then error messages will be output.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The example below removes pin overlaps for all pins on the soft macro alu1

```
prompt> remove_fp_pin_overlaps -cells [get_cells alu1]
```

The example below removes pin overlaps for top-level pins (i.e. terminals) only. Soft macro pins are left untouched.

```
prompt> remove_fp_pin_overlaps -pins [get_terminals *]
```

SEE ALSO

`sort_fp_pins(2)`

`remove_fp_pin_overlaps`
1442

remove_fp_plan_group_padding

Deletes the padding from plan groups.

SYNTAX

```
status_value remove_fp_plan_group_padding  
plan_groups
```

Data Types

plan_groups collection or list

ARGUMENTS

plan_groups
Specifies a collection of plan groups on which to remove padding.

DESCRIPTION

This command removes both internal and external padding on all specified plan groups.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes padding on a collection of plan groups named group_a.

```
prompt> remove_fp_plan_group_padding group_a
```

SEE ALSO

`create_fp_plan_group_padding(2)`

remove_fp_rail_stacked_via

Removes the selected power network stacked vias from the design based on the stacked via reduction results from the **reduce_fp_rail_stacked_via** command. These stacked vias are removed to reduce congestion.

SYNTAX

```
int remove_fp_rail_stacked_via
```

ARGUMENTS

none

DESCRIPTION

Removes the selected power network stacked vias from the design based on the stacked via reduction results from the **reduce_fp_rail_stacked_via** command. Before you use this command to actually remove the selected vias, you can preview the stacked via removal results in terms of reducing congestion, voltage (IR) drop and Electromigration (EM).

EXAMPLES

The following example removes the selected stacked vias from **reduce_fp_rail_stacked_via**.

```
prompt> remove_fp_rail_stacked_via
```

SEE ALSO

[reduce_fp_rail_stacked_via\(2\)](#)

remove_fp_rail_voltage_area_constraints

Removes the multi-voltage power network synthesis (PNS) constraints in the specified voltage area(s).

SYNTAX

```
status remove_fp_rail_voltage_area_constraints
[-voltage_area voltage_area]
[-all]
-layer string
```

Data Types

voltage_area collection or list

ARGUMENTS

-voltage_area *voltage_area*
Specify the voltage area name(s). This option is mutually exclusive with the **-all** option; you must specify only one.

-all
Remove multi-voltage PNS constraints in all voltage area(s). This option is mutually exclusive with the **-voltage_area** option; you must specify only one.

DESCRIPTION

This command removes the multi-voltage PNS constraints in specified voltage area(s).

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to remove the multi-voltage PNS constraints in all voltage area(s).

```
prompt> remove_fp_rail_voltage_area_constraints -all
```

SEE ALSO

```
set_fp_rail_voltage_area_constraints(2)
set_fp_rail_constraints(2)
set_fp_block_ring_constraints(2)
synthesize_fp_rail(2)
```

remove_fp_relative_location

Removes previously set relative location constraint(s).

SYNTAX

```
status remove_fp_relative_location  
[-name constraint_name]  
[-target_cells cells]
```

Data Types

<i>constraint_name</i>	string
<i>cells</i>	collection

ARGUMENTS

-name *constraint_name*
Specifies name of the relative location constraint to remove. By default, if no option is specified for this command, all relative location constraints are removed.

-target_cells *cells*
This option specifies the collection of macro cells whose relative location constraints are to be removed. By default, if no option is specified for this command, all relative location constraints are removed.

DESCRIPTION

The **remove_fp_relative_location** command removes specified or all relative location constraints previously set by **set_fp_relative_location** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to remove relative location constraint named "rp1" and the relative location constraint set on all cells whose names match "k_cell*".

```
prompt>remove_fp_relative_location \  
      -name rp1 \  
      -target_cells [get_cells "k_cell*"]
```

SEE ALSO

set_fp_relative_location(2)
extract_fp_relative_location(2)

remove_fp_relative_location

remove_fp_virtual_pad

Remove virtual power or ground pads for PNA and PNS.

SYNTAX

```
status remove_fp_virtual_pad
[-nets nets]
[-layer layer]
[-point {x y}]
[-all]
```

ARGUMENTS

```
-nets nets
      Specifies the net name(s) of the power or ground virtual pads to be removed.

-layer layer
      Specifies the layer name of the virtual pad to be removed.

-point {x y}
      Specifies the location of the virtual pad to be removed. The unit in the {x
      y} coordinate is micron.

-all
      Remove all virtual pads.
```

DESCRIPTION

Removes the virtual power and ground pads created by **create_fp_virtual_pad** command for PNS or PNA based on nets, layer and location.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to remove a virtual pad for net VDD on the metal layer M6 at the location {560.00 485.40}.

```
prompt> remove_fp_virtual_pad\
-nets VDD\
-layer M6\
-point {560.00 485.40}
```

SEE ALSO

`analyze_fp_rail(2)`

```
create_fp_virtual_pad(2)
synthesize_fp_rail(2)
```

```
remove_fp_virtual_pad
1448
```

remove_fp_voltage_area_constraints

Resets the feedthrough constraints for the specified voltage areas to the default values.

SYNTAX

```
status remove_fp_voltage_area_constraints
```

ARGUMENTS

The **remove_fp_voltage_area_constraints** command has no arguments.

DESCRIPTION

This command resets the feedthrough constraints for the specified voltage areas to the default values. You specify the voltage area feedthrough constraints with the **set_fp_voltage_area_constraints** command. The **route_global** and **analyze_fp_routing** commands use these constraints when creating logical pins on voltage areas.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example resets the feedthrough constraints for all voltage areas in the current design to the default values.

```
prompt> remove_fp_voltage_area_constraints
```

SEE ALSO

```
analyze_fp_routing(2)
report_fp_voltage_area_constraints(2)
route_global(2)
set_fp_voltage_area_constraints(2)
```

remove_from_collection

Removes objects from a collection, resulting in a new collection. The base collection remains unchanged.

SYNTAX

```
collection remove_from_collection
base_collection
object_spec
```

Data Types

<i>base_collection</i>	collection
<i>object_spec</i>	string

ARGUMENTS

base_collection

Specifies the base collection to be copied to the result collection. Objects matching *object_spec* are removed from the result collection.

object_spec

Specifies a list of named objects or collections to remove. The object class of each element in this list must be the same as in the base collection. If the name matches an existing collection, the collection is used. Otherwise, the objects are searched for in the database using the object class of the base collection.

DESCRIPTION

The **remove_from_collection** command removes elements from a collection, creating a new collection.

If the base collection is homogeneous, any element of the *object_spec* that is not a collection is searched for in the database using the object class of the base collection. If the base collection is heterogeneous, then any element of the *object_spec* that is not a collection is ignored.

If nothing matches the *object_spec*, the resulting collection is a copy of the base collection. If everything in *base_collection* matches the *object_spec*, the result is the empty collection.

For background on collections and querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example from PrimeTime gets all input ports except "CLOCK".

```
prompt> set cPorts [remove_from_collection [all_inputs] CLOCK]
{"in1", "in2"}
```

SEE ALSO

`add_to_collection(2)`
`collections(2)`
`query_objects(2)`

remove_from_rp_group

Removes an item (cell, relative placement group, or keepout) from the specified relative placement groups.

SYNTAX

```
status remove_from_rp_group
rp_groups
-leaf cell_name
-hierarchy group_name
[-instance instance_name]
-keepout keepout_name
```

Data Types

<i>rp_groups</i>	list or collection
<i>cell_name</i>	string
<i>group_name</i>	string
<i>instance_name</i>	string
<i>keepout_name</i>	string

ARGUMENTS

rp_groups
Specifies the relative placement groups from which to remove an item. The groups must all be in the same design.
If you do not specify this argument, no items are removed.

-leaf cell_name
Specifies the name of a leaf cell to remove from the specified relative placement groups. This option cannot be used with any other option.

-hierarchy group_name
Specifies the name of the relative placement group to remove from the specified relative placement groups.
This option can be used with the **-instance** option, but is mutually exclusive with **-leaf** and **-keepout**.

-instance instance_name
Specifies the name of the hierarchical cell that contains the instantiated relative placement group specified in the **-hierarchy** option.

-keepout keepout_name
Specifies the name of the keepout to remove from the specified relative placement groups. This option cannot be used with any other option.

DESCRIPTION

This command removes an item from specified relative placement groups. The item can be either a leaf cell, a relative placement group (included or instantiated), or a keepout. This command is supported only for designs that do not contain multiply-

instantiated designs. Relative placement usage is available with Design Compiler Ultra.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **remove_from_rp_group** to remove a cell from an existing relative placement group.

```
prompt> get_rp_groups ripple::grp_ripple
{ripple::grp_ripple}
prompt> remove_from_rp_group ripple::grp_ripple\
-leaf carry_in_1
1
```

SEE ALSO

```
add_to_rp_group(2)
create_rp_group(2)
get_rp_groups(2)
remove_rp_groups(2)
write_rp_groups(2)
```

remove_generated_clock

Removes a generated_clock object.

SYNTAX

```
string remove_generated_clock
-all |
clock_list
```

Data Types

clock_list list

ARGUMENTS

-all
Specifies that all the generated clocks be removed.

clock_list
Provides a list of generated clock names.

DESCRIPTION

This command removes the generated clocks in the design. If the generated clocks are expanded, the actual clocks are also deleted. All the attributes set on generated clocks (**false_paths** **multicycle_paths**, and so on) are also removed.

To create generated clock in the design, use the **create_generated_clock** command.

To show information about clocks and generated clocks in the design, use the **report_clock** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes the generated clock GEN1 from the design.

```
prompt> remove_generated_clock GEN1
```

The following example removes all the generated clocks from the design.

```
prompt> remove_generated_clock -all
```

SEE ALSO

[create_generated_clock\(2\)](#)

[remove_generated_clock](#)

```
report_clock(2)
```

remove_host_options

Remove host or pool definitions created by **set_host_options**.

SYNTAX

```
status remove_host_options
[-all]
[-name options_name]
[name]
```

Data Types

options_name string

ARGUMENTS

-all

Specifies that all host options should be deleted.

-name *options_name*

The name of the set of options to be deleted. It is an error to give both **-name** and **-all**.

DESCRIPTION

The **remove_host_options** command is used to unset the parameters set by the **set_host_options** command.

If the **-name** argument is given, any host/pool options of that name will be deleted.

If the **-all** argument is given, all host/pool options will be deleted, and the **-max_cores** value for the main (parent) job will be unset.

SEE ALSO

set_host_options(2)
report_host_options(2)

remove_ideal_latency

Removes ideal latency information from the specified objects.

SYNTAX

```
string remove_ideal_latency
[-rise | -fall] [-min | -max] object_list | -all
```

Data Types

object_list list

ARGUMENTS

-rise | -fall

Specifies that rise or fall ideal latency should be removed. By default, ideal latency is removed for both rise and fall ideal latency. The **-rise** and **-fall** options are mutually exclusive.

-min | -max

Specifies that maximum or minimum ideal latency should be removed. By default, it is removed for both minimum and maximum delay analysis. The **-min** and **-max** options are mutually exclusive.

object_list

Specifies a list of ports or pins from which to remove ideal latency.

-all

Remove ideal network latency from all objects.

DESCRIPTION

Removes from specified objects the user-specified ideal latency that was previously set by the **set_ideal_latency** command. See the **set_ideal_latency** man page for more details. You must either specify an *object_list* or use **-all**.

You can remove selected portions of ideal latency by specifying applicable **-rise**, **-fall**, **-min**, and **-max** options.

To list ideal latency values, use the **report_ideal_network** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes ideal latency from the output pin named *Z* of cell instance *U1/U2/U3*.

```
prompt> remove_ideal_latency {U1/U2/U3/Z}
```

The following example removes only rise ideal latency information from a port named A.

```
prompt> remove_ideal_latency -rise {A}
```

SEE ALSO

```
current_design(2)
remove_ideal_network(2)
remove_ideal_transition(2)
report_ideal_network(2)
report_timing(2)
set_auto_disable_drc_nets(2)
set_ideal_net(2)
set_ideal_network(2)
set_ideal_transition(2)
```

remove_ideal_net

Restores the ideal nets set by the **set_ideal_net** or **set_ideal_network -no_propagate** command to their initial nonideal state from the specified nets in the current design.

SYNTAX

```
status remove_ideal_net  
net_list
```

Data Types

net_list list

ARGUMENTS

net_list

Specifies a list of net names from which to remove the **ideal_net** attribute. These nets must be visible from the current design.

DESCRIPTION

Removes the **ideal_net** attribute from the individual nets specified in *net_list*; or restores the ideal nets that are set by the **set_ideal_net** command or the **set_ideal_network -no_propagate** command to their initial nonideal state from the specified nets in *net_list*. Those nets must be visible from the current design.

Ideal nets are networks of nets that are free from the `max_capacitance` and `max_fanout` design rule constraints. Ideal nets are useful to reduce DRC violations caused by clock trees, because these networks usually have high `max_capacitance` and `max_fanout` violations.

To remove the **auto_disable_drc_net** attribute from nets, use **set_auto_disable_drc_nets -none**. The **reset_design** command removes all attributes from the design, including the **ideal_net** and **auto_disable_drc_net** attributes. By default, the tool still treats clock networks as ideal nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the **ideal_net** attribute from individual nets in the design CLOCK_GEN:

```
prompt> current_design CLOCK_GEN  
prompt> remove_ideal_net [get_nets]
```

SEE ALSO

`reset_design(2)`
`set_auto_disable_drc_nets(2)`
`set_dont_touch(2)`
`set_dont_touch_network(2)`
`set_ideal_net(2)`

remove_ideal_network

Removes a set of ports or pins in an ideal network in the current design. Cells and nets in the transitive fanout of the specified objects are no longer treated as ideal.

SYNTAX

```
int remove_ideal_network  
object_list | -all
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of objects (pins or ports) that are sources of an ideal network. If more than one object name is specified, enclose the objects in quotes or braces ({}). The source objects can be input ports on the design or any internal pin except pins at hierarchical boundaries. These objects must be visible from the current design.

This argument and the **-all** option are mutually exclusive.

-all

Removes all ideal networks from the current design.

This option and the *object_list* argument are mutually exclusive.

DESCRIPTION

This command removes the ideal network designation from ports or pins in an ideal network.

Ideal networks, which are an extension of ideal nets, incorporate automatic propagation of the **ideal** attribute. You specify only the source ports or source pins of the network. All nets, cells, and pins on the transitive fanin of these objects are treated as ideal by the **compile** command.

The **ideal_network** attribute is automatically spread by the tool and respread as needed during optimizations. The **remove_ideal_network** command returns to normal part or all of a network that was previously marked as ideal using the **set_ideal_network** command. See the **set_ideal_network** man page for details about the propagation rules.

In addition to disabling timing update and timing optimizations, all cells in the ideal network are set with the **dont_touch** attribute. When part or all of the network is restored to normal using **remove_ideal_network**, the original **dont_touch** status of cells is restored.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets up an ideal network on objects in the design CLOCK_GEN and then removes part of the network:

```
prompt> current_design CLOCK_GEN
prompt> set_ideal_network {port1 port2
prompt> remove_ideal_network port2
```

SEE ALSO

```

set_ideal_network(2)
set_ideal_transition(2)
```

remove_ideal_transition

Removes ideal transition information from the specified objects.

SYNTAX

```
string remove_ideal_transition
[-rise | -fall] [-min | -max] object_list | -all
```

Data Types

object_list list

ARGUMENTS

-rise | -fall

Specifies that rise or fall ideal transition should be removed. By default, ideal transition is removed for both rise and fall ideal transition. The **-rise** and **-fall** options are mutually exclusive.

-min | -max

Specifies that maximum or minimum ideal transition should be removed. By default, ideal transition is removed for both maximum and minimum ideal transition. The **-min** and **-max** options are mutually exclusive.

object_list

Specifies a list of ports or pins from which to remove ideal transition.

-all

Remove ideal network transition from all objects.

DESCRIPTION

Removes from specified objects the user-specified ideal transition that was previously set by the **set_ideal_transition** command. See the **set_ideal_transition** man page for more details.

You can remove selected portions of ideal transition by specifying applicable **-rise**, **-fall**, **-min**, and **-max** options.

To list ideal transition values, use the **report_ideal_network** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes ideal transition from the output pin named *Z* of cell instance *U1/U2/U3*.

```
prompt> remove_ideal_transition {U1/U2/U3/Z}
```

The following example removes only rise ideal transition information a port named A.

```
prompt> remove_ideal_transition -rise {A}
```

SEE ALSO

```
current_design(2)
remove_ideal_latency(2)

```

remove_ignore_cell_timing

Undoes the effects of set_ignore_cell_timing

SYNTAX

```
int remove_ignore_cell_timing  
cell_list
```

Data Types

cell_list list

ARGUMENTS

cell_list

Specifies a collection of cells which are no longer should be ignored by timing related commands.

DESCRIPTION

The **remove_ignore_cell_timing** command removes the "ignore_cell" attribute on the cell(s) that was previously marked as ignored by the **set_ignore_cell_timing** command. By removing the ignore_cell attribute, the cells are now part of the network, and should not be ignored by the timing related commands.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following example set an ignored attribute on a cell in the design CLOCK_GEN, this cell thus be ignored by timing related commands:

```
prompt> current_design CLOCK_GEN  
prompt> set_ignore_cell_timing cell12  
prompt> vBremove_ignore_cell_timing cell12
```

SEE ALSO

set_ignore_cell_timing(2).

remove_ignored_layers

Removes ignored routing layers in congestion analysis and RC estimation. This command can also remove the design minimum and maximum routing layers if those layers have been already set.

SYNTAX

```
int remove_ignored_layers
list_of_layers
[-all]
[-min_routing_layer]
[-max_routing_layer]
```

ARGUMENTS

list_of_layers
Lists the routing layers that should no longer be ignored during congestion analysis and RC estimation.

[-all]
Specifies that no routing layers should be ignored during congestion analysis and RC estimation.

[-min_routing_layer]
Removes the setting for the design minimum routing layer.

[-max_routing_layer]
Removes the setting for the design maximum routing layer.

DESCRIPTION

You can specify routing layers to be ignored during congestion analysis and RC estimation. This command removes the ignored setting from some or all of these layers.

Note that congestion analysis and RC estimation require at least one horizontal and one vertical layer are not ignored.

You can also use this command to remove the settings for the design minimum and maximum routing layers.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> remove_ignored_layers -all
```

SEE ALSO

`set_ignored_layers(2)`
`report_ignored_layers(2)`
`report_lib(2)`

remove_input_delay

Removes input delay on pins or input ports.

SYNTAX

```
int remove_input_delay
[-clock clock] [-clock_fall] [-level_sensitive]
[-rise]
[-fall]
[-max]
[-min]
port_pin_list
```

Data Types

<i>clock</i>	string or collection of one object
<i>port_pin_list</i>	list

ARGUMENTS

-clock *clock*
Removes delay information relative to the specified clock edge. If **-clock** is not specified, all input delay is removed. To remove input delay that has no relative clock, use **remove_input_delay -clock ""**.
The clock can be specified as either a string or a collection of one object.

-clock_fall
Removes input delay relative to the clock falling edge. If **-clock_fall** is not specified, input delay relative to the clock rising edge is removed.
This option is only used with the **-clock** option.

-level_sensitive
Removes level-sensitive input delay. If this option is not used, only nonlevel-sensitive input delay is removed.
This option is only used with the **-clock** option.

-rise
Removes rising delay on *port_pin_list*. If you do not specify **-rise** or **-fall**, both rising and falling delays are removed.

-fall
Removes falling delay on *port_pin_list*. If you do not specify **-rise** or **-fall**, both rising and falling delays are removed.

-max
Removes maximum input delays on *port_pin_list*. If you do not specify **-max** or **-min**, both maximum and minimum input delays are removed.

-min
Removes minimum input delays on *port_pin_list*. If you do not specify **-max** or **-min**, both maximum and minimum input delays are removed.

```
port_pin_list
    Specifies list of port or pin names in the current design. Input delay is
    removed from each object in port_pin_list. To specify more than one object,
    enclose the objects in quotes ("") or braces ({}).
```

DESCRIPTION

This command removes input delay values for objects in the current design. Set the input delay using the **set_input_delay** or the **characterize** command. By default, all input delay on each object in *port_pin_list* is removed. To restrict the input delay values that are removed, use the **-clock**, **-clock_fall**, **-min**, **-max**, **-rise**, or **-fall** options.

Use the **report_port** command to list input delays associated with ports. Use the **report_design** command to list input delays of internal pins.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes all input delay values from all input ports in the current design:

```
prompt> remove_input_delay all_inputs()
```

The following example removes input maximum rise delay values from IN1, IN3, and BIDIR12:

```
prompt> remove_input_delay -max -rise {IN1 IN3 BIDIR12}
```

The following example, removes all input delay for the IN1 port, relative to the falling edge of CLK2.

```
prompt> remove_input_delay -clock [get_clocks CLK2] -clock_fall \
           [get_ports "IN1"]
```

The following example removes all input delay not relative to any clock for port IN4.

```
prompt> remove_input_delay -clock "" IN4
```

```

```
remove_input_delay  
1470
```

remove_io_constraints

Removes previously set physical constraints

SYNTAX

```
status remove_io_constraints
[-cell name]
[-pin_only]
[-pad_only]
[-chiplevel_pad_only]
[objects]
```

Data Types

<i>name</i>	string
<i>objects</i>	collection

ARGUMENTS

-cell *name*

Specifies the Milkyway cell name or plan group whose physical constraints will be removed. The default behavior removes the current cell's physical constraints.

-pin_only

Indicates only pin physical constraints will be removed. The **-pin_only**, **-pad_only** and **chiplevel_pad_only** options are mutually exclusive. Use only one.

-pad_only

Indicates only pad physical constraints will be removed. The **-pin_only**, **-pad_only** and **chiplevel_pad_only** options are mutually exclusive. Use only one.

-chiplevel_pad_only

Indicates only chip-level pad physical constraints will be removed. The **-pin_only**, **-pad_only** and **chiplevel_pad_only** options are mutually exclusive. Use only one.

objects

Specifies the pin or pad which physical constraints are removed. If this option is not specified, the physical constraints for all pins, pads and chip level pads are removed.

DESCRIPTION

This command allows you to remove all previously set physical constraints in the currently active Milkyway cell or specified Milkyway cell for the specified pins, pads or chip-level pads. If no argument is specified, this command removes all physical constraints for all pins, pads and chip-level pads.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the physical constraints for all pins and pads in the current design.

```
prompt> remove_io_constraints
```

The following example removes the physical constraints for all pins.

```
prompt> remove_io_constraints -pin_only
```

SEE ALSO

remove_io_pin_overlap

Spreads pins so that they do not overlap one another and have spacing violations.

SYNTAX

```
int remove_io_pin_overlap
```

ARGUMENTS

No arguments needed, the command gets current design.

DESCRIPTION

Spreads pins so that they do not overlap one another and have spacing violations. Does not move the location of fixed pins and respects placement blockages. Pins inside placement blockages are considered illegal and are moved.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the command in default settings:

```
prompt> remove_io_pin_overlap  
1
```

SEE ALSO

remove_isolate_ports

Removes the specified ports from the list of ports that are isolated in the current design.

SYNTAX

```
int remove_isolate_ports  
port_list
```

Data Types

port_list list

ARGUMENTS

port_list

Specifies the ports that will be removed from the list of ports that are isolated in the current design. Port isolation must have been requested for these ports using the **set_isolate_ports** command.

DESCRIPTION

The **remove_isolate_ports** command removes the specified ports from the list of ports that are isolated in the current design.

This command will not remove the isolation cell inserted by a previous **compile** command. The isolation cell will be removed by a subsequent **compile** command issued after the **remove_isolate_ports** command, if the **max_area** attribute has been set on the current design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the port "qout" from the list of ports being isolated.

```
prompt> remove_isolate_ports qout
```

SEE ALSO

```
report_isolate_ports(2)  
reset_design(2)  
set_isolate_ports(2)  
set_max_area(2)
```

remove_isolation_cell

Removes specified isolation cell or cells from design.

SYNTAX

```
int remove_isolation_cell  
[-force]  
-object_list cells
```

Data Types

cells list

ARGUMENTS

```
-force  
Forces deletion of ISO/ELS cells for cells marked dont touch.  
  
-object_list cells  
Use this option to specify the list of cells to be removed. This argument is  
mandatory.
```

DESCRIPTION

The **remove_isolation_cell** command is used to remove isolation cell or enabled level shifters. This command can be used only on unqualified design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all isolation cells with string ISO in their name.

```
prompt> remove_isolation_cell -obj [get_cells *ISO*]
```

SEE ALSO

`insert_isolation_cell(2)`

remove_keepout_margin

Removes keepout margin of specified type for the specified cells/lib cells in the design.

SYNTAX

```
int remove_keepout_margin
[-type hard | soft]
[-derived]
object_list
```

Data Types

object_list list

ARGUMENTS

-type hard | soft

Specifies the type of keepout to be removed. The valid values are **hard** and **soft**. By default, keepouts of both soft and hard types are removed for the cells or library cells.

-derived

This option is provided to remove the user specified pin count based derived keepout margin values. User defined pin count based keepout margin values are set using the `-tracks_per_macro_pin` and/or `-max_padding_per_macro` and/or `-min_padding_per_macro` options of **set_keepout_margin** command.

object_list

Describes the list of cells or library cells for which keepouts are to be removed. The keepouts are deleted for all cells with `FIXED_PLACEMENT` or library cells in this list.

DESCRIPTION

This command removes keepouts for the specified cells/library cells. If you do not use the **-type** option, keepouts of both soft and hard type are deleted for the specified cells/library cells. If this command is run to delete a keepout when none exists for a cell/library cell, a warning message is printed out and no action is taken.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **remove_keepout_margin** command.

remove_keepout_margin

1476

```
prompt> report_keepout_margin MY_CELL -type hard
Cell Name: MY_CELL
*****
Hard Keepout - 10.0000 10.0000 10.0000 10.0000
prompt> remove_keepout_margin -type hard MY_CELL
prompt> report_keepout_margin MY_CELL -type soft
Cell Name: MY_CELL
*****
Soft Keepout - 10.0000 10.0000 10.0000 10.0000
prompt> remove_keepout_margin -type hard MY_LIB_CELL
The following example will remove all derived keepouts in the design.
prompt> remove_keepout_margin -derived *S
```

SEE ALSO

`get_attribute(2)`
`report_keepout_margin(2)`
`set_keepout_margin(2)`

remove_left_right_filler_rule

removes left-right filler cell insertion rules.

SYNTAX

```
integer remove_left_right_filler_rule  
-lib_cell
```

ARGUMENTS

```
-lib_cell cell_list  
cell_list must refers to a collection of cell references. The left-right  
filler cell rule removal will be applied to the cells specified in this list.
```

DESCRIPTION

Use this command to remove the left-right filler rules of the current design. A left (right) filler rule inserts a left (right) filler cell to the immediate left (right) side of a standard cell. A left or right filler cell is often used to avoid certain design rule spacing problems.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes left right filler rule for library cell stdcellA and stdcellB

```
prompt> remove_left_right_filler_rule -lib_cell {stdcellA, stdcellB}
```

SEE ALSO

```
insert_stdcell_filler(2)  
set_left_right_filler_rule(2)  
report_left_right_filler_rule(2)
```

remove_level_shifters

Removes all of the level shifters from the design.

SYNTAX

```
integer remove_level_shifters
[-force]
```

ARGUMENTS

-force

Removes level shifters even if they are set with the **dont_touch** attribute, or if they were instantiated in the original netlist.

DESCRIPTION

This command removes all level shifters from the design, except those that you explicitly marked as **dont_touch** and those that you instantiated in the original netlist. To remove level shifters that have these restrictions, use the **-force** option.

This command provides the capability to remove pre-existing or tool-inserted level shifters, allowing you to perform custom voltage adjustments by manually inserting different level-shifter cells.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command removes level shifters in a design:

```
prompt> remove_level_shifters
```

SEE ALSO

```
check_level_shifters(2)
insert_level_shifters(2)
set_level_shifter_strategy(2)
set_level_shifter_threshold(2)
```

remove_license

Removes a licensed feature.

SYNTAX

```
status remove_license  
feature_list
```

Data Types

```
feature_list      list
```

ARGUMENTS

```
feature_list  
      Specifies the list of features to remove. If you specify more than one  
      feature, they must be enclosed in braces ({}).  
      By looking at your key file, you can determine all of the features licensed  
      at your site.
```

DESCRIPTION

Removes the specified licensed features from the features you currently are using.

The **list_licenses** command provides a list of the features that you currently are using.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This example removes the multivoltage license.

```
prompt> remove_license {Galaxy-MV}
```

SEE ALSO

```
check_license(2)  
license_users(2)  
list_licenses(2)  
get_license(2)
```

remove_map_power_switch

Removes library cells from the mapping definition for the specified power switch, which was previously defined by using the **map_power_switch** command. This command is supported only in UPF mode.

SYNTAX

```
status remove_map_power_switch
power_switch_name
-all | -lib_cells cells
```

Data Types

<i>power_switch_name</i>	string
<i>cells</i>	collection

ARGUMENTS

power_switch_name

Specifies the name of the power switch whose mapped library cells are to be removed.

-all

Removes the mapping definition for the specified power switch. This option is mutually exclusive with the **-lib_cells** option; you must specify one of these options.

-lib_cells *cells*

Specifies the library cells to be removed from the mapping definition for the specified power switch. This option is mutually exclusive with the **-all** option; you must specify one of these options.

DESCRIPTION

The *remove_map_power_switch* command removes library cells from the mapping definition for the specified power switch, which was previously defined by using the *map_power_switch* command.

This command returns a 1 if successful and returns a 0 otherwise.

EXAMPLES

The following example removes all the library cells from the mapping definition for the SW1 power switch.

```
prompt> remove_map_power_switch SW1 -all 1
```

The following example removes the lib2A/switch2A library cell from the SW1 power switch.

```
prompt>remove_map_power_switch SW1 -lib_cells lib2A/switch2A 1
```

SEE ALSO

```
create_power_switch(2)
get_power_switches(2)
map_power_switch(2)
report_power_switch(2)
```

remove_mim_property

Removes multiply-instantiated-module data for selected instances. These instances will no longer be treated as multiply-instantiated-modules; that is, each will now refer to a unique master.

SYNTAX

```
status remove_mim_property
{collection_of_cells}
```

Data Types

collection_of_cells collection

ARGUMENTS

{*collection_of_cells*}
Specifies a list of hierarchical cells under the current parent cell for which multiply-instantiated-module data is to be removed. If the command does not find a cell, it issues a warning.

DESCRIPTION

This command deletes any data pointing to a multiply-instantiated-module master for each cell in the specified collection. The cell becomes unique.

This command affects the database. The tool saves the changes it makes if the parent cell is saved.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example first unifies the cells by using the **uniquify_fp_mw_cel** command and stores a reference to the master cell for instA, instB, instC and instD. The **report_mim** command then lists these instances as multiply-instantiated modules. The **remove_mim_property** command alters the multiply-instantiated module status of instA and instB. They are now treated as unified and using the **report_mim** command does not list them.

```
prompt> uniquify_fp_mw_cel\
-store_mim_property [get_cells {instA instB instC instD}]
prompt> report_mim
instA
instB
instC
```

```
instD
prompt> remove_mim_property [get_cells {instA instB}]
prompt> report_mim
```

SEE ALSO

[report_mim\(2\)](#)
[uniquify_fp_mw_cel\(2\)](#)

remove_mw_cel

Removes Milkyway designs from the design library.

SYNTAX

```
status remove_mw_cel
[-hierarchy [-check_only]]
[-version_kept count]
[-verbose]
[-all_versions]
[-all_view]
mw_cel_list
```

Data Types

<i>count</i>	integer
<i>mw_cel_list</i>	list

ARGUMENTS

-hierarchy

Deletes both the specified top-level design and all of its subdesigns. By default, the command deletes only the specified designs and retains subdesigns
This option can not work with **-all_views** and **-all_versions**. If **mw_cel_list** option is used with this option, it can only contain one Milkyway design. Moreover, the version number and view name of the Milkyway design will be ignored. As for the view name, the hierarchical remove can only operate on CEL view. As for the version number, hierarchical remove can only remove all versions or retain last version, which is controlled by **-version_kept** option.

-check_only

Prints the list of Milkyway designs, versions, and views, but does not delete any data. If you are unsure about the result of the command, run this option first, before performing the purge operation. This option is valid only when used with the **-hierarchy** option.

-version_kept count

Specifies how many recent versions to keep. The value must be equal or greater than **0**. Value **0** removes all versions. When used with the **-hierarchy** option, the only valid values are **0** or **1**.
The default behavior differs for hierarchical removal (specified by using the **-hierarchy** option) and nonhierarchical removal. For hierarchical removal, all versions are deleted if you do not specify the **-version_kept** option. For nonhierarchical removal, only the latest version is deleted if you do not specify the **-version_kept** option.

-verbose

Prints the possible cause when the command fails to remove a specified Milkyway design. Currently, this option is effective only when you use it with the **-hierarchy** option.

```

-all_versions
    Removes all versions of specified Milkyway designs. This option can not work
    with -hierarchy option.

-all_view
    Removes all views of specified Milkyway designs. By default, the command
    removes only the specified view. This option can not work with -hierarchy
    option.

mw_cel_list
    Specifies the Milkyway designs to remove. If you also use the -hierarchy
    option with this option, the designs to remove must be top-level designs. You
    can specify a Milkyway design by name, pattern, or collection. For more
    information, see the EXAMPLES section, below.
    When use with -hierarchy option, only one Milkyway design can be specified.
    And the version number or view name of the Milkyway design will be ignored.
    The view name is always CEL view and the version number is controlled by -
    version_kept option.
    When not use with -hierarchy option, only the specified view and version will
    be deleted.

```

DESCRIPTION

This command removes specified Milkyway designs from the current library. Before removing designs, you must make sure that the designs are closed.

The **-version_kept** option allows you to remove older versions of the Milkyway design while keeping newer ones (to free up disk space).

The **-hierarchy** option allows you to remove or purge a Milkyway design and its whole hierarchical tree.

NOTE: Please be aware that the behavior of **remove_mw_cel** differs depending on whether you specify the **-hierarchy** option. The default command behavior deletes the specified version of the Milkyway design, but when called with the **-hierarchy** option, the command deletes all versions or non-latest versions of the Milkyway designs controlled by **-version_kept**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the latest version of the Milkyway designs whose names start with *test*.

```

prompt> get_mw_cels test*
{"test1", "test2"}
prompt> remove_mw_cel test* -verbose
Removed mw_cel test1.

```

```
Removed mw_cel test2.
```

```
1
```

The following example removes version **1** of a design named *test1*. In this case, *test1* has two versions. After removing one version, you can still get a Milkyway design collection based on its remaining version.

```
prompt> remove_mw_cel "test1.CEL;1" -verbose
Removed mw_cel test1.CEL;1.
1
prompt> get_mw_cels *
{"test1"}
```

The following example removes the design named *chip_top* and all of its subdesigns from the current design library.

```
prompt> remove_mw_cel -hierarchy chip_top
Deleting the cell: nand_macro ...
Deleting the cell: chip_top ...
1
```

The following example purges the old versions of the design named *chip_top* and all of its subdesigns from the current design library. Only the latest version of these designs is kept.

```
prompt> remove_mw_cel -hierarchy -version_kept 1 \
chip_top
Purging the cell: nand_macro ...
Purging the cell: chip_top ...
1
```

SEE ALSO

```

save_mw_cel(2)
```

remove_net

Removes nets from the *current design*.

SYNTAX

```
int remove_net  
net_list | -all
```

Data Types

net_list list

ARGUMENTS

net_list
A list of nets to be removed from the current design. Each net name must exist in the current design. You must specify either *net_list* or **-all**.

-all
Causes the removal of all nets in the current design.

DESCRIPTION

This command removes nets or net instances from the *current design*. Net connections to pins or ports are disconnected.

You cannot remove bused nets with the **remove_net** command.

To create nets, use the **create_net** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example in uses **remove_net** in the current design:

```
prompt> get_nets **  
{NET0 NET1 NET2 NET3 MY_CHECK PARITY}  
  
prompt> remove_net "N*"  
Removing net 'NET0' in design 'my_design'.  
Removing net 'NET1' in design 'my_design'.  
Removing net 'NET2' in design 'my_design'.  
Removing net 'NET3' in design 'my_design'.  
  
prompt> get_nets **  
{MY_CHECK PARITY}
```

The following example removes all remaining nets in the current design:

```
prompt> remove_net -all
Removing net 'MY_CHECK' in design 'my_design'.
Removing net 'PARITY' in design 'my_design'.

prompt> get_nets **
{ }
```

The following example removes a net instance:

```
prompt> remove_net {U1/MY_NET U2/MY_NET}
Removing net 'U1' in design 'foo_1'.
Removing net 'U2' in design 'foo_2'.
```

SEE ALSO

`create_net(2)`
`current_design(2)`

remove_net_routing

Removes all routing (vias and segments) for specific nets.

SYNTAX

```
int remove_net_routing  
list_of_nets
```

Data Types

list_of_nets list

ARGUMENTS

list_of_nets
Lists the net names for which to remove routing. Substitute the list you want for *list_of_nets*.

DESCRIPTION

This command removes all routing (vias and segments) for specific nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes routing for nets named *sig1* and *sig2*.

```
prompt> remove_net_routing {sig1 sig2}
```

SEE ALSO

`set_net_routing_rule(2)`

remove_net_routing_layer_constraints

Removes routing layer constraints for specific nets.

SYNTAX

```
int remove_net_routing_layer_constraints  
list_of_nets
```

Data Types

list_of_nets list

ARGUMENTS

list_of_nets
Lists the net names for which to remove the routing layer constraints.
Substitute the list you want for *list_of_nets*.

DESCRIPTION

This command removes routing layer constraints for specific nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the routing layer constraints for a net named *netA*.

```
prompt> remove_net_routing_layer_constraints {netA} \
```

SEE ALSO

`report_net_routing_layer_constraints(2)`
`set_net_routing_layer_constraints(2)`

remove_net_shape

Removes objects of net shapes. The objects could be specified by a collection or by name.

SYNTAX

```
status_value remove_net_shape
[-verbose]
net_shapes
```

Data Types

net_shapes list

ARGUMENTS

-verbose
Prints additional messages.

net_shapes
Specifies a nonempty collection of handles to net shapes, or the name of the net shape.

DESCRIPTION

This command removes all specified net shapes, and then returns 1 if successful, or 0 if it fails.

If invalid handles occur in the input handle collection, the command line interpreter removes them from the collection and invokes the **remove_net_shape** command with the updated collection.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes net shapes:

```
prompt> set a [get_net_shapes -of_objects n300
{ "VWIRE#6682", "HWIRE#7196", "VWIRE#6683" }
```

```
prompt> remove_net_shape $a
1
```

The following example removes net shapes specified by a pattern list:

```
remove_net_shape
1492
```

```
prompt> remove_net_shape {HWIRE#7170 HWIRE#7171} -verbose
Removed net shape HWIRE#7170.
Removed net shape HWIRE#7171.
1
```

SEE ALSO

`create_net_shape(2)`
`get_net_shapes(2)`
`remove_user_shape(2)`

remove_net_timing_spacing

Remove timing spacing flags.

SYNTAX

```
status remove_net_timing_spacing
```

DESCRIPTION

This command removes timing spacing flags for all nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> remove_net_timing_spacing
```

remove_objects

Removes a list of objects

SYNTAX

```
status remove_objects  
objects
```

ARGUMENTS

objects
Specifies the objects to be removed.

DESCRIPTION

Removes a list of objects from the current design.

Note: only non-netlist objects can be removed i.e objects which have representations in the netlist cannot be removed.

See `get_edit_property(2)` for a list of deletable objects.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the selected objects:

```
> remove_objects [get_selection]
```

SEE ALSO

remove_output_delay

Removes output delay on pins or output ports.

SYNTAX

```
int remove_output_delay
[-clock clock [-clock_fall] [-level_sensitive]]
[-rise]
[-fall]
[-max]
[-min]
port_pin_list
```

Data Types

<i>clock</i>	string or collection of one object
<i>port_pin_list</i>	list

ARGUMENTS

-clock *clock*
Removes delay information relative to the specified clock edge. If **-clock** is not specified, all output delay is removed. To remove output delay that has no relative clock, use **remove_output_delay -clock ""**. You can specify the clock as either a string or a collection of one object.

-clock_fall
Removes output delay relative to the clock falling edge. If you do not specify **-clock_fall**, output delay relative to the clock rising edge is removed. This option is only used with the **-clock** option.

-level_sensitive
Removes level-sensitive output delay for the specified clock. If this option is not used, non-level-sensitive output delay is removed.

-rise
Removes rising delay on *port_pin_list*. If you do not specify **-rise** or **-fall**, both rising and falling delays are removed.

-fall
Removes falling delay on *port_pin_list*. If you do not specify **-rise** or **-fall**, both rising and falling delays are removed.

-max
Removes maximum output delays on *port_pin_list*. If you do not specify **-max** or **-min**, both maximum and minimum output delays are removed.

-min
Removes minimum output delays on *port_pin_list*. If you do not specify **-max** or **-min**, both maximum and minimum output delays are removed.

```
port_pin_list
    Specifies a list of port or pin names in the current design. Output delay is
    removed from each object in port_pin_list. To specify more than one object,
    enclose the objects in quotes ("") or braces ({}).
```

DESCRIPTION

This command removes output delay values for objects in the current design. Output delay is set by the **set_output_delay** or the **characterize** command. By default, all output delay on each object in *port_pin_list* is removed. To restrict the removed output delay values, use the **-clock**, **-clock_fall**, **-min**, **-max**, **-rise**, or **-fall** option.

To list output delays associated with ports, use the **report_port** command.

To list output delays of internal pins, use the **report_design** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes all output delay values from all output ports in the current design:

```
prompt> remove_output_delay [all_outputs]
```

This example removes output maximum rise delay values from OUT1, OUT3, and BIDIR12.

```
prompt> remove_output_delay -max -rise {OUT1 OUT3 BIDIR12}
```

This example removes all output delay for port OUT1, relative to the falling edge of CLK2:

```
prompt> remove_output_delay -clock [get_clocks CLK2] \
           -clock_fall [get_ports OUT1]
```

This example removes all output delay not relative to any clock for the OUT2 port:

```
prompt> remove_output_delay -clock "" OUT2
```

SEE ALSO

```

```

remove_pg_network

Removes or changes the hierarchical power and ground network.

SYNTAX

```
status remove_pg_network
-net list_of_pg_net
hier_cell_list | -top
```

Data Types

hier_cell_list collection

ARGUMENTS

-net *list_of_pg_net*

Specifies an existing power or ground net for network removal. You can specify only one net, which must be a scalar (single bit) net. The net, specified as its full name, can be at any hierarchy level. If you do not specify this option, the tool issues an error message and stops.

hier_cell_list

Specifies a list of hierarchical cell instances from which to remove the power and ground network. The tool removes the power and ground network from the specified hierarchical cells and their children. If any of the specified cells does not exist in the current design or is not a hierarchical cell, the tool issues an error message and stops. If any of the specified cells exists in the current design and is a hierarchical cell, but is not in the PG network, the tool issues a warning message and continues.

-top

If this option is specified, the tool ignores *hier_cell_list* option and the operation will be performed on the entire design.

DESCRIPTION

This command removes hierarchical PG connections from the specified hierarchical cell instances and their children or from the entire design if you do not specify any hierarchical cell instances.

For each specified hierarchical cell and their children, the command removes the power and ground network by performing the following tasks:

1. Disconnects the PG nets from the leaf pins inside the cell
2. Deletes the PG nets that connect to pins inside the cell
3. Disconnects the PG nets from the ports of the cell
4. Deletes the cell ports connected to the power and ground network

The removed hierarchy cell ports can be recreated by *create_pg_network* command.

This command supports the recovery of tie connections. All signal pins connected on the network are re-connected to tie before the PG network is removed.

This command does not remove top-level PG port. To remove the top-level PG port, you must use the **remove_port** command.

EXAMPLES

The following example uses the **remove_pg_network** command to remove the existing VDD connection from the specified hierarchical cell instances. The **all_connected** command is used to verify the Milkyway net connections before and after running **remove_pg_network**.

```
prompt> all_connected [get_pin -all m2/VDD]
{VDD}
prompt> remove_pg_network -net VDD "m2/m21 m1/m11"
prompt> all_connected [get_pin -all m2/VDD]
Warning: No pin objects matched 'm2/VDD' (SEL-004)
```

The following example uses the **remove_pg_network** command to remove the VDDC net connection from the specified hierarchical cell. The **all_connected** command is used to verify the net connections before and after running **remove_pg_network**.

```
prompt> all_connected [get_pin -all m2/VDDC]
{VDDC}
prompt> remove_pg_network -net VDDC "m2"
prompt> all_connected [get_pin -all m2/VDDC]
Warning: No pin objects matched 'm2/VDDC' (SEL-004)
```

```

remove_physical_bus

Removes physical buses.

SYNTAX

```
status remove_physical_bus
physical_bus_list | -all
```

Data Types

physical_bus_list list

ARGUMENTS

physical_bus_list

Specifies the physical buses to remove. The *physical_bus_list* value can include collections of physical_bus type, patterns that use wildcards, or certain command names. The *physical_bus_list* and **-all** options are mutually exclusive.

-all

Specifies to remove all physical buses in the current design. The *physical_bus_list* and **-all** options are mutually exclusive.

DESCRIPTION

This command removes all specified physical buses. You can specify physical buses by using their name patterns or collections of physical_bus type which can be generated by commands like **get_physical_bus** and **get_selection**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the use of a wildcard pattern that removes all physical buses.

```
prompt> remove_physical_bus *
1
```

SEE ALSO

```
create_physical_bus(2)
get_physical_buses(2)
get_selection(2)
report_physical_bus(2)
```

remove_physical_bus

1500

update_physical_bus(2)

remove_pin_guides

Deletes the specified pin guides from the design.

SYNTAX

```
status remove_pin_guides
-all | patterns
[-verbose]
```

Data Types

patterns collection

ARGUMENTS

-all

Removes all pin guides.

patterns

Specifies the collection of pin guides to delete.

-verbose

Turns on verbose output.

If -all is specified the total number of pin guides deleted is output; otherwise, the names of the deleted pin guides are output.

DESCRIPTION

This command deletes the specified pin guides from the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all pin guides.

```
prompt> remove_pin_guides -all
```

The following example removes selected pin guides.

```
prompt> remove_pin_guides [get_selection]
```

SEE ALSO

1503

remove_pin_name_synonym

Removes pin name synonym definitions.

SYNTAX

```
status remove_pin_name_synonym  
[-all]  
[synonym_list]
```

Data Types

synonym_list list

ARGUMENTS

-all

Removes all the pin name synonym definitions. One of **-all** and **synonym_list** is required, and they are mutually exclusive.

synonym_list

Removes pin name synonym definitions that match one of the pin name synonym strings in the list. One of the **-all** and **synonym_list** is required, and they are mutually exclusive.

DESCRIPTION

The **remove_pin_name_synonym** command deletes some or all pin name synonym definitions.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes pin name synonyms.

```
prompt> set_pin_name_synonym SYN_CD CD
1
prompt> set_pin_name_synonym SYN_QN QN
1
prompt> set_pin_name_synonym -full_name mid1/bot1/LSR0P_at_bot/SYN_R mid1/bot1/

remove_placement

Unplace cells in the core area.

SYNTAX

```
status remove_placement
[-object_type {standard_cell | macro_cell | all}]
[-new_location {top_right | origin | center}]
```

ARGUMENTS

-object_type {standard_cell | macro_cell | all}
Unplaces macro cells, standard cells, or all of them. Default is to unplace all types of cells.

-new_location {top_right | origin | center}
The location where tool moves the cells. Default is top_right, unplaced macro cells are on the top side of chip, and unplaced standard cells are on the right side of chip. If "origin" is specified, unplaced standard cells coordinates are set to (0,0). If "center" is specified, unplaced standard cells coordinates are set to the center of the chip.

DESCRIPTION

Unplace cells in the core area. The command does not uplace fixed & dont_touch cells.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example moves all standard cells outside the chip at the right boundary. Macros are not moved.

```
prompt> remove_placement -object_type standard_cell
1
```

SEE ALSO

remove_placement_blockage

Remove placement blockages.

SYNTAX

```
int remove_placement_blockage
[-verbose]
[-name name]
patterns | -all
```

Data Types

patterns list

ARGUMENTS

-verbose

Prints more messages.

-name name

Specifies a name by which this command finds and removes a placement blockage. Notice that the name should be a real name specified by you when creating the same placement blockage with the `create_placement_blockage -name` command, not a run time name, such as "pb#7789". The "-name", "patterns" and "-all" are mutually exclusive.

patterns

Specifies the placement blockages to remove. The patterns can be a collection handle of blockage, or other formats, such as the following:
* or pb#* Means all placement blockages.
pb#7789Means one placement blockage whose object_id is 7789.
The "patterns", "-all" and "-name" are mutually exclusive.

-all

If specified, this command removes all placement blockages in the current design. The "-all", "patterns" and "-name" are mutually exclusive.

DESCRIPTION

This command removes all specified placement blockages.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example create a blockage for placement.

`remove_placement_blockage`

1508

```
prompt> remove_placement_blockage -all
1

prompt> remove_placement_blockage [get_placement_blockages \
? * -within {{2 2} {25 25}}
1
```

SEE ALSO

`create_route_guide(2)`
`get_placement_blockages(2)`
`get_route_guides(2)`
`remove_route_guide(2)`

remove_plan_groups

Removes plan groups from the current design.

SYNTAX

```
int remove_plan_groups  
[-verbose]  
-all objects
```

Data Types

objects string

ARGUMENTS

-verbose
Specifies to print information about what are being deleting.

-all
Specifies to remove all plan groups from the current design.

objects
Specifies plan group objects to be removed. You can use the *get_plan_groups* command to specify the objects.

DESCRIPTION

This command removes plan groups from the current design. If you specify the **-all** option, all plan groups are to be removed from the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes plan groups named *timer/decode0* and *timer/decode1*.

```
prompt> remove_plan_groups -verbose {timer/decode0 timer/decode1  
prompt> remove_plan_groups [get_plan_groups *
```

SEE ALSO

get_plan_groups (2)

remove_pnet_options

Removes options set by the **set_pnet_options** command.

SYNTAX

```
int remove_pnet_options
```

ARGUMENTS

The **remove_pnet_options** command has no arguments.

DESCRIPTION

This command removes the options set on the metal layers and the design using the **set_pnet_options** command. The pnet options are removed from the design and are not set to defaults. For more details about defaults, see the man page for the **set_pnet_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example prints out the different options set on the metal layers with the **set_pnet_options** command.

```
prompt> remove_pnet_options  
1
```

SEE ALSO

```
legalize_placement(2)  
report_pnet_options(2)  
set_pnet_options(2)
```

remove_port

Removes ports from the current design or its subdesign.

SYNTAX

```
int remove_port  
port_list
```

Data Types

```
port_list      list
```

ARGUMENTS

```
port_list  
Specifies a list of ports to be removed from the current design. Each port  
name must exist in the current design.
```

DESCRIPTION

Removes ports from the current design or its subdesign.

Scalar (single bit) ports that are components of a bused port cannot be removed using this command.

To create ports, use **create_port**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **remove_port** to remove ports from the current design.

```
prompt> get_ports **  
{A1 A2, B1, B2, OUT1}  
  
prompt> remove_port "B**"  
Removing port 'B1' in design 'my_design'.  
Removing port 'B2' in design 'my_design'.  
1  
prompt> get_ports **  
{A1 A2 OUT1}
```

In the following example, ports are removed from the subdesign MID. U1 is an instance of the design MID.

```
prompt> remove_port [get_ports U1/p1 U1/p2]
Removing port 'U1/p1' in design 'MID'.
Removing port 'U1/p2' in design 'my_design'.
1
```

SEE ALSO

[create_port\(2\)](#)
[current_design\(2\)](#)

remove_power_domain

Removes the specified power domains.

SYNTAX for UPF mode

```
status remove_power_domain
```

```
[-verbose]  
[-scope instance_name]  
[power_domains]
```

Data Types for UPF mode

<i>instance_name</i>	string
<i>power_domains</i>	list

SYNTAX for Non-UPF Mode

```
status remove_power_domain
```

```
domain_name | -all
```

Data Types for Non-UPF mode

<i>domain_name</i>	string
--------------------	--------

ARGUMENTS

-verbose

This option is available only in UPF mode. Prints additional messages.

-scope *instance_name*

This option is available only in UPF mode. Specifies the scope in which the power domain is to be deleted. The instance name is the name of a hierarchical cell.

By default, the power domain is deleted from the current scope.

If this option is specified, the **power_domains** option must also be specified and it only accepts simple name, not collection.

domain_name

This option is available only in non-UPF mode. Specifies the name of the power domain to be deleted. The name should be a simple (non-hierarchical) name. This option is mutually exclusive with the **-all** option.

If the specified power domain does not exist in the current design, the command fails.

If there are any supply ports, supply nets, or power switches associated with the specified power domain, the command fails.

power_domains

This option is available only in UPF mode. Specify the power domains to be

remove_power_domain

deleted. The option value could be a collection of power domains or name patterns.
The command fails if it could not find any specified power domain.
If this option is not specified, the command will remove all power domains under current scope.
If **-scope** option is also specified, the value of this option must be a simple name, not collection.
If there are any supply ports, supply nets, or power switches associated with the specified power domain, the command fails.

-all

This option is available only in non-UPF mode. Deletes all power domains in the current design. This option is mutually exclusive with the **domain_name** argument.

DESCRIPTION

The **remove_power_domain** command enables you to remove existing power domains (or all power domains, in non-UPF mode). Before you can delete a power domain, you must remove all relationships between the power domain and any supply ports, supply nets, power switches, or child power domains.

This command returns a 1 if successful and returns a 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following UPF-mode example removes the PD1 power domain in current scope.

```
prompt> remove_power_domain PD1  
1
```

The following UPF-mode example removes power domains whose name start with PD in all scopes:

```
prompt> remove_power_domain [get_power_domains -hier PD*] -verbose  
Removed power domain 'PD1' successfully.  
Removed power domain 'REG_BLK/PD2' successfully.  
Removed power domain 'STACK_BLK/PD_child' successfully.  
1
```

The following non-UPF mode example creates the TOP_DOMAIN power domain and then deletes it.

```
prompt> create_power_domain TOP_DOMAIN  
1  
prompt> create_power_domain SUB_DOMAIN -power_down \  
        -power_down_ctrl [get_nets pd_ctrl] \  
        -power_down_ack [get_nets pd_ack] \  
1
```

```
-object_list [get_cells mid1]
1
prompt> get_power_domains
{TOP_DOMAIN SUB_DOMAIN}
prompt> remove_power_domain TOP_DOMAIN
Error: Design-level power domain TOP_DOMAIN cannot be removed until
all instance power domains are removed. (MV-074)
0
prompt> remove_power_domain SUB_DOMAIN
Removing Power Domain 'SUB_DOMAIN'
1
prompt> remove_power_domain TOP_DOMAIN
Removing Power Domain 'TOP_DOMAIN'
1
```

remove_power_net_info

Deletes power net info.

SYNTAX

```
int remove_power_net_info  
name  
-all
```

Data Types

name string

ARGUMENTS

name
The name of the power net info to be deleted. Mutually exclusive with -all option.

-all
Deletes all the power nets in the current design. Mutually exclusive with *name* option.

DESCRIPTION

The **remove_power_net_info** command deletes a named power net info or all the power net info for the current design.

EXAMPLES

The following examples use the command to create and remove power nets.

```
prompt> create_power_net_info VSS_net -gnd  
1  
prompt> create_power_net_info VDD_net -power  
1  
prompt> remove_power_net_info VSS_net  
1  
prompt> remove_power_net_info -all  
1
```

SEE ALSO

[report_power_net_info \(2\)](#)
[create_power_net_info \(2\)](#)

remove_power_switch

Removes a power switch from the specified power domain. This command is supported only in UPF mode.

SYNTAX

```
status remove_power_switch  
[-verbose]  
[power_switches]  
[-domain domain_name]
```

Data Types

<i>power_switches</i>	list
<i>domain_name</i>	string

ARGUMENTS

-verbose	Prints additional messages.
-domain <i>domain_name</i>	Specifies the power domain of the power switch to be deleted. If the specified power domain does not exist in the current scope, the command fails. If this option is specified, the power_switches option must be a simple name, not collection.

DESCRIPTION

The *remove_power_switch* command removes existing power switches.

This command returns a 1 if successful and returns a 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the SW1 power switch.

```
prompt> remove_power_switch SW1 -verbose  
Removed power switch 'SW1' from power domain 'PD1' successfully.  
1
```

SEE ALSO

create_power_switch(2)

remove_power_switch

1518

```
get_power_switches(2)
report_power_switch(2)
set_scope(2)
```

remove_preferred_routing_direction

Removes the preferred routing direction for the given routing layer(s).

SYNTAX

```
string remove_preferred_routing_direction  
-layers list_of_layers
```

ARGUMENTS

-layers *list_of_layers*
Specify the list/collection of layer(s) for which the preferred routing directions is to be removed.

DESCRIPTION

This command removes the preferred routing direction for the routing layer(s) specified from the design & the preferred routing direction for those routing layers defaults to the one specified in the reference library.

Note: This command will issue warning for layers that do not have a defined preferred routing direction in the reference library, as there needs to exist atleast one preferred routing direction setting for each layer.

Note: This command will issue suitable warnings whenever adjacent layers have the same routing direction after the execution of the command.

Note: This command removes the setting from the design, & NOT the reference library. The change is to the persistent data and will be reflected in the design database whenever the user saves the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the preferred routing direction for layers "m1" & "m2"

```
prompt> remove_preferred_routing_direction -layers {m5 m6}
```

SEE ALSO

```
report_preferred_routing_direction(2)  
set_preferred_routing_direction(2)
```

remove_propagated_clock

Removes a propagated clock specification.

SYNTAX

```
string remove_propagated_clock  
object_list
```

Data Types

object_list list

ARGUMENTS

object_list
Lists clocks, ports, pins, or cells.

DESCRIPTION

Removes the propagated clock specification from clocks, ports, pins, or cells in the current design. The **set_propagated_clock** command specifies that delays be propagated through the clock network to determine latency at register clock pins. If this is not specified, ideal clocking is assumed. Ideal clocking means clock networks have a user-specified latency (from the **set_clock_latency** command), or zero latency by default. Propagated clock latency is normally used for post layout, after final clock tree generation. Ideal clock latency provides an estimate of the clock tree for pre-layout.

To specify an ideal latency, you can also use **set_clock_latency**; this overrides the propagated clock specification for an object.

To see **propogated_clock** attributes on clocks, use **report_clock -skew**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The example removes propagated clock specifications from all clocks in the design.

```
prompt> remove_propagated_clock all_clocks[]
```

SEE ALSO

```
set_clock_latency(2)  
set_propagated_clock(2)  
create_clock(2)  
remove_attribute(2)
```

```
reset_design(2)
report_clock(2)
```

```
remove_propagated_clock
1522
```

remove_qor_snapshot

Removes an existing QoR snapshot of timing, drc, area, power, etc. The remove utility deletes snapshots from the location specified by the **icc_snapshot_storage_location** variable.

NOTE: This is the new version of the **remove_qor_snapshot** command that supports both multicorner-multimode designs as well as non-multicorner-multimode designs.

SYNTAX

```
void remove_qor_snapshot  
[-name name]  
[-all ]
```

ARGUMENTS

```
-name name  
The name of the qor snapshot to be removed.  
  
-all  
Remove all snapshots for this design.
```

DESCRIPTION

This command removes one or more qor snapshot(s).

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

In the following example, **remove_qor_snapshot** will remove QoR snapshot named *preroute* which is saved under design/snapshot directory.

```
prompt> remove_qor_snapshot -name preroute
```

SEE ALSO

```
create_qor_snapshot(2)  
report_qor_snapshot(2)
```

remove_rail_maps

Removes all rail map data from the current session.

SYNTAX

```
status remove_rail_maps
```

ARGUMENTS

none

DESCRIPTION

This command removes all rail map data from the current IC Compiler session, releasing any memory previously allocated for the maps. This command can be helpful in reducing the memory in use when the user no longer needs to see the rail maps. Use **read_rail_maps** to reload the rail maps, if needed.

EXAMPLES

The following example shows how to remove a map from memory.

```
prompt> remove_rail_maps
```

SEE ALSO

[analyze_rail\(2\)](#)
[read_rail_maps\(2\)](#)

remove_route_by_type

Remove route by type.

SYNTAX

```
status remove_route_by_type
[-nets nets]
[-signal_detail_route]
[-signal_user]
[-clock_ring]
[-clock_strap]
[-clock_tie_off]
[-clock_user]
[-pg_ring]
[-pg_strap]
[-pg_tie_off]
[-pg_user]
[-pg_std_cell_pin_conn]
[-pg_macro_io_pin_conn]
[-keep_pg_vias]
[-keep_pg_pins_at_boundary]
[-bus]
[-shield]
[-keep_frozen_net]
```

Data Types

nets string

ARGUMENTS

```
-nets nets
      Remove route by type for a collection of nets. The value can be a string or
      a list of strings.

-signal_detail_route
      Remove signal routes that are of type detail wire.

-signal_user
      Remove signal routes that are of type user.

-clock_ring
      Remove clock ring.

-clock_strap
      Remove clock strap.

-clock_tie_off
      Remove clock tie off detail route.

-clock_user
      Remove clock user entered.
```

```
-pg_ring
    Remove pg ring.

-pg_strap
    Remove pg strap.

-pg_tie_off
    Remove pg tie off.

-pg_user
    Remove pg user entered.

-pg_std_cell_pin_conn
    Remove pg std cell connections.

-pg_macro_io_pin_conn
    Remove pg macro/io pin connections.

-keep_pg_vias
    Don't remove pg vias.

-keep_pg_pins_at_boundary
    Keep pg boundary pins generated by preroute std cell.

-bus
    Remove bus type.

-shield
    Remove shield type.

-keep_frozen_net
    Don't remove frozen net.
```

DESCRIPTION

This command deletes routes of specified types of all nets or that of specified net names.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> remove_route_by_type -signal_detail_route
```

remove_route_guide

Removes route guides.

SYNTAX

```
int remove_route_guide
[-verbose]
[-name name]

```

Data Types

patterns list

ARGUMENTS

-verbose

Prints additional messages.

-name *name*

Specifies a name by which this command finds and removes a route guide. Notice that the name should be a real name specified by you when creating the same route guide with the `create_route_guide -name` command, not a run time name, such as "rg#7689".

The "-name" and "patterns" are mutually exclusive.

patterns

Specifies the route guides to remove. The patterns can be a collection handle of route guides, or other formats, such as the following examples:

* or rg* removes all route guides.

rg#7789 removes one route guide whose object_id is 7789.

The "patterns" and "-name" options are mutually exclusive.

-all

Specifies to remove all route guides in the *current design*.

DESCRIPTION

This command removes all specified route guides.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the route guides specified by the `get_route_guides` command.

```
prompt> remove_route_guide [get_route_guides *] \  
-within {{2 2} {25 25}}  
1
```

The following example removes all route guides.

```
prompt> remove_route_guide -all  
1
```

SEE ALSO

`create_placement_blockage(2)`
`create_route_guide(2)`
`get_placement_blockages(2)`
`get_route_guides(2)`
`remove_placement_blockage(2)`

remove_routing_blockage

Removes the specified routing blockages.

SYNTAX

```
status remove_routing_blockage
[-verbose]
patterns
```

Data Types

patterns list

ARGUMENTS

-verbose
Prints additional messages.

patterns
Specifies the routing blockages. You can specify the patterns by using the following formats:
* A collection of routing blockages
* An asterisk (*), which indicates all routing blockages
* A string
For example, RB_1234 matches the routing blockage named RB_1234

DESCRIPTION

This command removes the specified routing blockages.

EXAMPLES

The following example removes all routing blockages within the rectangle with the lower-left corner at {2 2} and the upper-right corner at {25 25}.

```
prompt> remove_routing_blockage \
[get_routing_blockages -within {{2 2} {25 25}}]
1
```

The following example removes all metal routing blockages.

```
prompt> remove_routing_blockage [get_routing_blockages -type metal]
1
```

SEE ALSO

`create_routing_blockage(2)`
`get_routing_blockages(2)`

remove_routing_rules

Removes nondefault routing rules in a design defined by the **define_routing_rule** command.

SYNTAX

```
int remove_routing_rules
[-all]
rule_name_list
```

Data Types

rule_name_list list

ARGUMENTS

-all
 Removes all nondefault routing rules.

rule_name_list
 Removes nondefault routing rules with the specified names.

DESCRIPTION

This command removes the nondefault routing rules defined in the design. If you use the **-all** option, all nondefault routing rules in the design are removed. If you specify a list of names, the nondefault routing rules in the list are removed.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the nondefault routing rule named *wire_rule1*.

```
prompt> remove_routing_rules wire_rule1
```

SEE ALSO

```
define_routing_rule(2)
report_routing_rules(2)
```

remove_row_type

Remove row type attribute on the specified rows.

SYNTAX

```
status remove_row_type
[-site site_name row_name_list]
```

Data Types

<i>site_name</i>	string
<i>row_name_list</i>	list

ARGUMENTS

-site *site_name*
Specifies the name of the site to remove row type of all rows with this name.
This option and the *row_name_list* are mutually exclusive; use only one.

row_name_list
Specifies row list with name pattern or a collection containing site rows to remove row type attribute. This argument and the **-site** option are mutually exclusive; use only one.

DESCRIPTION

The **remove_row_type** command removes row type attribute on a specified list of rows or on the rows of the specified site.

When you want to remove the row type of all the rows in a site, use the **-site** option.

EXAMPLES

The following example shows how to remove row type on the specified rows.

```
prompt>remove_row_type {ROW_0 ROW_1 ROW_2 ROW_4}
```

The following example shows how to remove row type for all rows in a specified site.

```
prompt>remove_row_type -site unit
```

SEE ALSO

`set_row_type(2)`

remove_rp_group_options

Removes relative placement (RP) group attributes from the specified relative placement groups.

SYNTAX

```
collection remove_rp_group_options
rp_groups
[-ignore]
[-x_offset]
[-y_offset]
[-compress]
```

Data Types

rp_groups list or collection

ARGUMENTS

rp_groups

Specifies the relative placement groups from which to remove the specified relative placement group attributes.

-ignore

Removes the **-ignore** attribute, which indicates that the tool is to ignore this relative placement group during placement and not treat it as a relative placement group.

-x_offset

Removes the **-x_offset** attribute of the relative placement group.

-y_offset

Removes the **-y_offset** attribute of the relative placement group.

-compress

Removes the **-compress** attribute of the relative placement group.

DESCRIPTION

This command removes the attributes of the relative placement groups. This command is supported only for designs that do not contain multiply-instantiated designs. This command returns a collection containing the relative placement groups for which attributes have changed. If attributes have not changed for any group, an empty string is returned.

Relative Placement usage is available with Design Compiler Ultra.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes attributes from a relative placement group.

```
prompt> remove_rp_group_options ripple::grp_ripple -ignore \
-x_offset -y_offset
{ripple::grp_ripple}
```

SEE ALSO

add_to_rp_group(2)
all_rp_groups(2)
create_rp_group(2)
get_rp_groups(2)
remove_from_rp_group(2)
remove_rp_groups(2)
set_rp_group_options(2)
write_rp_groups(2)

remove_rp_groups

Removes a list of relative placement (RP) groups.

SYNTAX

```
status remove_rp_groups
rp_groups | -all
[-hierarchy]
[-quiet]
```

Data Types

rp_groups list or collection

ARGUMENTS

rp_groups

Specifies a list of relative placement groups to remove.
This argument and the **-all** option are mutually exclusive.

-all

Specifies that all relative placement groups will be removed.
This option cannot be used with either the *rp_groups* argument or the **-hierarchy** option.

-hierarchy

Specifies that all relative placement groups within the hierarchy of the groups in *rp_groups* will be removed. By default, subgroups are not removed.
This option cannot be used with the **-all** option.

-quiet

Turns off messages that would otherwise be issued as relative placement groups are removed.

DESCRIPTION

The **remove_rp_groups** command removes a list of relative placement groups. When a relative placement group is removed, the memory it occupies is freed, so the object is no longer in the design.

Relative placement usage is available with Design Compiler Ultra.

Note that memory is freed to be reused by this same process. However, memory is not returned to the operating system until you exit the tool.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **remove_rp_groups** to delete a relative placement group.

```
prompt> get_rp_groups
{mul::grp_mul ripple::grp_ripple example3::top_group}

prompt> remove_rp_groups ripple::grp_ripple
Removing rp group 'ripple::grp_ripple'
1

prompt> get_rp_groups ripple::grp_ripple
Error: Can't find object 'grp_ripple'. (UID-109)

prompt> remove_rp_groups -all
Removing rp group 'mul::grp_mul'
Removing rp group 'example3::top_group'
1
```

SEE ALSO

[add_to_rp_group\(2\)](#)
[create_rp_group\(2\)](#)
[write_rp_groups\(2\)](#)

remove_scaling_lib_group

Removes any previously specified scaling_lib_group from the current design, or from a subdesign.

SYNTAX

```
status remove_scaling_lib_group
[-object_list objects]
```

Data Types

objects list

ARGUMENTS

-object_list *objects*

Specifies the cells or top level ports on which to remove any requested scaling library groups. If you do not use this option, group(s) are removed from the top level design.

DESCRIPTION

The **remove_scaling_lib_group** command removes the scaling library group set on the design objects previously by **set_scaling_lib_group** commands. After this removal, the tool will not do scaling between libraries for voltage and/or temperature.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> remove_scaling_lib_group -object_list top/inv
```

SEE ALSO

```
define_scaling_lib_group(2)
set_scaling_lib_group(2)
create_scenario(2)
set_operating_conditions(2)
```

remove_scan_def

Removes any scan chain data stored in Milkyway.

SYNTAX

```
status remove_scan_def
```

DESCRIPTION

This command removes any scan chain data stored in the Milkyway based on the current open CEL. This scan chain data has been previously initialized by using the **read_def** command to read a scan Design Exchange Format (DEF) file or by using the **trace_scan_chain** command. When you use the **remove_scan_def** command, the netlist remains the same.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

```
check_scan_chain(2)
optimize_dft(2)
read_def(2)
report_scan_chain(2)
trace_scan_chain(2)
```

remove_scan_pin_type

Removes the scan-in or scan-out type if set on the specified pin.

SYNTAX

```
status remove_scan_pin_type  
[-pin pin | -ref_pin physical_lib_pin]
```

Data Types

<i>pin</i>	collection
<i>physical_lib_pin</i>	collection

ARGUMENTS

-pin *pin*
Specifies a collection of one pin.

-ref_pin *physical_lib_pin*
Specifies a collection of one physical lib pin.

DESCRIPTION

This command removes the scan-in or scan-out type if it is set on the given pin or physical lib pin. The type is removed from the reference library cell so corresponding pins on all instances of the reference cell have the scan type removed. You can use the **is_scan_in** and **is_scan_out** attributes to check the scan_type of a pin for scan-in and scan-out, respectively.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the scan type from pin Z of a buffer timer/buffd1.

```
prompt> remove_scan_pin_type -pin [get_pins timer/buffd1/Z]
```

SEE ALSO

```
get_attribute(2)  
get_physical_lib_pins(2)  
get_pins(2)  
set_scan_pin_type(2)  
trace_scan_chain(2)
```

remove_scenario

Removes a scenario from memory.

SYNTAX

```
status remove_scenario  
[scenario_name | -all]
```

ARGUMENTS

scenario_name	Specifies the name of the scenario to be deleted.
-all	Specifies that all scenarios are to be deleted.

DESCRIPTION

Removes a scenario from memory. All the scenario-specific constraints defined in that scenario are deleted.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following example uses **remove_scenario** to delete a scenario.

```
prompt> create_scenario MODE1  
prompt> create_scenario MODE2  
prompt> all_scenarios  
  
MODE 1 MODE 2  
  
prompt> remove_scenario -all  
prompt> all_scenarios  
  
>
```

SEE ALSO

all_scenarios(2)
current_scenario(2)
remove_scenario(2)

remove_sdc

Removes all Synopsys Design Constraints (SDC).

SYNTAX

```
int remove_sdc  
[-keep_parasitics]
```

ARGUMENTS

-keep_parasitics

Use this option, when the rc network has been created and there is no need to remove it.

DESCRIPTION

Removes all constraints as defined in the current version of Synoptys Design Constraints.

The removal of annotated parasitics is expected when using the **remove_sdc** command. If you need this information after removing SDC information, reannotate the parasitics data by running **extract_rc** or **read_parasitics** again.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following command removes all SDC information from the current design:

```
prompt> remove_sdc
```

SEE ALSO

```
current_design(2)  
remove_attribute(2)  
remove_clock(2)  
remove_ideal_latency(2)

set_max_delay(2)  
set_max_fanout(2)  
set_max_time_borrow(2)  
set_max_transition(2)
```

remove_sdc

remove_site_row

Removes specified site rows or all site rows defined in the current design.

SYNTAX

```
string remove_site_row
[row_name_list]
```

Data Types

row_name_list list

ARGUMENTS

row_name_list

Specifies one or more row names to remove. The default is to remove all site rows in the current design.

DESCRIPTION

This command removes site rows in the current design. If you do not specify a row name, all site rows and corresponding base array in the current design are removed.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all site rows in the current design.

```
prompt> remove_site_row
```

SEE ALSO

`create_site_row(2)`

remove_skew_group

Removes the user-defined skew group.

SYNTAX

```
remove_skew_group
[-name skew_group_name]
```

Data Types

skew_group_name string

ARGUMENTS

```
-name skew_group_name
      Removes the specified skew group from the design.
```

DESCRIPTION

This command removes the specified skew group from the design.

EXAMPLES

The following example removes the skew group named grp1.

```
prompt> remove_skew_group -name grp1
in -0.25i
```

SEE ALSO

```
set_skew_group(2)
report_skew_group(2)
```

remove_stdcell_filler

Deletes standard, pad, and tap filler cells.

SYNTAX

```
status remove_stdcell_filler
-stdcell | -pad | -tap
[-bounding_box {{llx lly} {urx ury}}]
```

Data Types

llx	float
lly	float
urx	float
ury	float

ARGUMENTS

-stdcell | -pad | -tap
Specifies the type of filler cells to delete. Specify stdcell to delete standard filler cells, pad to delete pad cells, and tap to delete tap cells, respectively.

-bounding_box {{llx lly} {urx ury}}
Indicates the lower left and upper right coordinates of the rectangle from where the filler cells are to be removed. If you do not specify this option, the working area is the entire chip.

DESCRIPTION

The **remove_stdcell_filler** command removes filler cells from the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes standard cell fillers from the specified area
prompt> remove_stdcell_filler -stdcell -boundingbox{{10 10} {500 500}}

SEE ALSO

```
insert_diode(2)
insert_ng_filler(2)
insert_pad_filler(2)
insert_stdcell_filler(2)
insert_well_filler(2)
```

remove_supply_net

Removes supply nets from the specified power domain. This command is supported only in UPF mode.

SYNTAX

```
status remove_supply_net
[-verbose]
[supply_nets]
[-domain domain_name]
```

Data Types

<i>supply_nets</i>	list
<i>domain_name</i>	list

ARGUMENTS

-verbose

Prints additional messages.

supply_nets

Specifies the supply nets to be deleted. The option value could be a collection of supply nets or name patterns.

The default value is '*' which matches all supply nets under current scope. The command fails if it could not find any specified supply nets.

-domain *domain_name*

Since one supply_net could be defined in more than one power_domains, this option specify in which power_domains the supply nets are to be deleted.

The command fails if it fails to find any specified power_domains.

This option is optional.

If this option is specified, all specified supply_nets are removed from these specified power_domains only. If there is any specified supply_nets which are not defined in the specified power_domains, these supply_nets will be skipped and they won't be removed from any power_domains.

If this option is not specified, all specified supply_nets will be removed from all power_domains in which they're defined.

DESCRIPTION

The *remove_supply_net* command removes an existing supply net in a power domain.

This command returns a 1 if successful and returns a 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the A_VDD supply net from the PD1 power domain.

```
prompt> remove_supply_net A_VDD -domain PD1  
1
```

The following example removes all supply nets that are defined in the PD1 power domain.

```
prompt> remove_supply_net [get_supply_nets -hier] \  
    -domain [get_power_domains PD1] -verbose  
Removed supply_net 'A_VDD' from power_domain 'PD1' successfully.  
Removed supply_net 'A_VSS' from power_domain 'PD1' successfully.  
Warning: Skipped to remove supply_net 'REG_BLK/A_VDD' since it is not  
defined in power_domain 'PD1'.  
Warning: Skipped to remove supply_net 'REG_BLK/A_VSS' since it is not  
defined in power_domain 'PD1'.  
1
```

You could also write the above example as follows:

```
prompt> remove_supply_net \  
    [get_supply_nets -hier -of_objects [get_power_domains PD1]] \  
    -domain [get_power_domains PD1] -verbose  
Removed supply_net 'A_VDD' from power_domain 'PD1' successfully.  
Removed supply_net 'A_VSS' from power_domain 'PD1' successfully.  
1
```

SEE ALSO

connect_supply_net(2)
create_supply_net(2)
get_supply_nets(2)
report_supply_net(2)
set_scope(2)
get_power_domains(2)

remove_supply_port

Removes a supply port from the scope of the specified power domain or the current scope. This command is supported only in UPF mode.

SYNTAX

```
status remove_supply_port
[-verbose]
[supply_ports]
[-domain domain_name]
```

Data Types

<i>supply_ports</i>	list
<i>domain_name</i>	string

ARGUMENTS

-verbose
Prints additional messages.

supply_ports
Specify the supply ports to be deleted. The option value could be a collection of supply ports or name patterns.
The default value is '*' which matches all supply ports under current scope.
The command fails if it could not find any specified supply port.

-domain *domain_name*
Specifies the power domain in whose scope the supply port is to be deleted.
If the specified power domain does not exist in the current scope, the command fails.
If this option is specified, the *supply_ports* option must be a simple name, not collection.

DESCRIPTION

The *remove_supply_port* command removes an existing supply port in the specified scope

The command returns 1 on success, and returns 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the VN1 supply port from the PD1 power domain.

```
remove_supply_port
```

```
1546
```

```
prompt> remove_supply_port VN1 -domain PD1  
1
```

The following example removes all supply ports in the current scope whose name begins with "VN".

```
prompt> remove_supply_port [get_supply_ports -hier VN*]  
1
```

SEE ALSO

`create_supply_port(2)`
`get_supply_ports(2)`
`report_supply_port(2)`
`set_scope(2)`

remove_target_library_subset

Removes target library subset constraints (including both the target library subset specified by library_list option and -milkyway_reflibs option) from root design or from specified instances.

SYNTAX

```
int remove_target_library_subset
[-object_list cells]
[-top]
```

ARGUMENTS

-object_list *cells*

Specifies the cells from which to remove the target library subset. The cells should be instances of hierarchical designs, subset restriction applies to those instances and their children. You must specify at least one from **-top** and **-object_list**. If neither **-top** nor **-object_list** is specified, command errors out.

-top

If specified, the target library subset is removed from the root design. You must specify at least one from **-top** and **-object_list**. If neither **-top** nor **-object_list** is specified, command errors out.

DESCRIPTION

Removes target library subset or milkyway reference library subset from the given instances, or the root design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the target_library subset from the root design and from bloock u1.

```
prompt> remove_target_library_subset -object_list [get_cells u1] -top
```

SEE ALSO

```
set_target_library_subset(2)
report_target_library_subset(2)
check_target_library_subset(2)
set_operating_conditions(2)
target_library(3)
```

remove_terminal

Removes terminals.

SYNTAX

```
status_value remove_terminal
terminals
[-verbose]
```

Data Types

terminals list

ARGUMENTS

terminals
Specifies patterns or a list of nonempty collections of handles to terminals.

-verbose
Prints more information.

DESCRIPTION

This command removes all specified terminals. If the input collection is empty, the command returns 0 to indicate failure.

If there are invalid handles in the input handle collection, the command-line interpreter removes them from the collection and invokes the **remove_terminal** command with the updated collection.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all terminals whose name matches *clock**:

```
prompt> remove_terminal clock*
1
```

SEE ALSO

`create_terminal(2)`
`get_terminals(2)`

remove_text

Removes text.

SYNTAX

```
int remove_text  
text_list | -all
```

Data Types

text_list list

ARGUMENTS

text_list
Specifies the text to remove. The *text_list* value can include collections of text type, patterns that use wildcards, or certain command names. The *text_list* and **-all** options are mutually exclusive.

-all
Specifies to remove all text in the current design. The *text_list* and **-all** options are mutually exclusive.

DESCRIPTION

This command removes all specified text. Users can specify text by using the name of text or collections of text type which can be generated by commands like *get_text* and *get_selection*.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the use of a pattern that removes the text object with *object_id* 6400.

```
prompt> remove_text TEXT#6400  
1
```

The following example shows the use of a wildcard pattern that removes all text.

```
prompt> remove_text *  
1
```

The following example shows the use of a wildcard pattern that removes all text that start with *TEXT#*.

```
prompt> remove_text TEXT#*
1
```

The following example firstly creates a collection containing text's bounding box within the specified rectangle {10 9} {45 15} then removes text in the collection.

```
prompt> remove_text [get_text \
? * -within {{10 9} {45 15}}
1
```

The following example removes all text.

```
prompt> remove_text -all
1
```

SEE ALSO

`create_text(2)`
`get_text(2)`

remove_tie_cells

Removes tie cells and changes their connected pins and ports in the Milkyway database.

SYNTAX

```
status remove_tie_cells
[-use_default_tie_net]
tie_cell_list
```

Data Types

tie_cell_list collection

ARGUMENTS

-use_default_tie_net

Connects the signal pins that were originally driven by the deleted tie cells to the default SNPS_LOGIC0 or SNPS_LOGIC1 nets. If you do not specify this option, the tool keeps the original nets driven by the tie pins and sets the net_type attribute for those nets to tie-low or tie-high.

tie_cell_list

Specifies a list of tie cell instances to be removed.

If any of the specified cells do not exist in the design or they are not tie cells, the tool issues a warning message and continues processing other cells in the specified tie cell list.

DESCRIPTION

Removes the specified tie cells. The signal pins that were originally driven by the deleted tie cells are connected to Milkyway tie-low or tie-high nets.

The signal pins can be either leaf pins or hierarchical pins.

By default, the command keeps the original net driven by the tie cells and sets the net_type attribute to tie-low or tie-high, as determined by the tie pin attribute.

If you specify the **-use_default_tie_net** option, tie nets become the default SNPS_LOGIC1 or SNPS_LOGIC0 nets. The original nets driven by the tie cells are deleted. If a tie cell is removed for a hierarchical port, the tie net name uses the port name as the prefix in addition to SNPS_LOGIC1 or SNPS_LOGIC0. For example, if a hierarchical port is named "Q" and it is tied low inside the hierarchical module, the tie net name becomes "Q_SNPS_LOGIC0".

EXAMPLES

The following example uses the **remove_tie_cells** command to remove all the existing tie cells.

The **get_cells** command is used to verify the tie cells before and after running the **remove_tie_cells** command.

```
prompt> all_tieoff_cells
{TIELOU1 TIELOU2 TIELOU3}
prompt> remove_tie_cells -use_default_tie_net [all_tieoff_cells]
prompt> get_cells {TIELOU1 TIELOU2 TIELOU3}
Warning: No cell objects matched 'TIELOU1' (SEL-004)
Warning: No cell objects matched 'TIELOU2' (SEL-004)
Warning: No cell objects matched 'TIELOU3' (SEL-004)
```

The following example uses the **remove_tie_cells** command to remove a collection of tie cells.

The **report_tie_nets** command is used to verify the new logic zero net after running the **remove_tie_cells** command.

The **get_nets** command is used to verify that the old nets connected to the deleted tie cells are also deleted.

```
prompt> get_nets -all U2/TIELOU1_net0
{U2/TIELOU1_net0}
prompt> remove_tie_cells -use_default_tie_net {U2/TIELOU0 U2/TIELOU1}
prompt> report_tie_nets
Design has 1 tie low net(s):
    net U2/SNPS_LOGIC0 connects to the following port(s) or pin(s):
        U2/U1/D
        U2/U1/NT
        U2/U4/S
prompt> get_nets -all U2/TIELOU1_net0
Warning: No net objects matched 'U2/TIELOU1_net0' (SEL-004)
```

SEE ALSO

connect_tie_cells(2)
disconnect_net(2)
remove_cell(2)

remove_track

Removes tracks.

SYNTAX

```
status remove_track
-all | patterns | -layer layer [-dir X | Y]
[-verbose]
```

Data Types

<i>patterns</i>	list
<i>layer</i>	string

ARGUMENTS

-all

Specifies to remove all tracks in the current design. The **-all** and *patterns* and **-layer** options are mutually exclusive. You can specify only one of these options.

patterns

Matches the track names in the current design against the specified patterns. You can specify the patterns by using the following formats:
* An asterisk (*), which indicates all tracks
* "TRACK_*" indicates all tracks
* Track names, which are in the format TRACK_object_id
The **-all** and *patterns* and **-layer** options are mutually exclusive. You can specify only one of these options.

-layer *layer*

Specifies the routing layer to use the routing tracks. You can use layer name, layer number, or a collection containing one layer object. The **-all** and *patterns* and **-layer** options are mutually exclusive. You can specify only one of these options.

-dir X | Y

Specifies the direction how routing tracks are placed. The valid values are **X** and **Y**; specify either. By default, the direction is the routing direction of the layer specified in the physical library. The option should be used with the option **-layer**.

-verbose

Prints additional messages.

DESCRIPTION

This command removes all specified tracks.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all tracks which lies inside {{2 2} {25 25}}.

```
prompt> remove_track [get_tracks -within {{2 2} {25 25}}]  
1
```

The following example removes all tracks which located on metal2.

```
prompt> remove_track [get_tracks -of_objects METAL2] -verbose  
Removing track TRACK_4683  
1
```

The following example removes routing tracks from a routing layer named m3 on the floorplan.

```
prompt> remove_track -layer m3  
Warning: Direction is not specified. Using the layer preferred direction.  
(MWUI-125)  
1  
prompt> remove_track -layer m3 -dir X  
1
```

SEE ALSO

```
create_track(2)

report_track(2)
```

remove_unconnected_ports

Removes unconnected ports or pins from cells, references, and subdesigns.

SYNTAX

```
int remove_unconnected_ports
cell_list
[-blast_buses]
```

Data Types

cell_list list

ARGUMENTS

cell_list

Specifies a list of cells or instances whose unconnected ports or pins are to be removed.

-blast_buses

Indicates that if a bus has a port that is unconnected, the bus is to be deleted, the unconnected ports are to be removed, and single-bit buses are to be created for the remaining ports.

DESCRIPTION

This command removes unconnected ports or pins from cells, references, and subdesigns. The current design must be linked and uniquified before you run this command. A port is considered unconnected if it is not connected on the inside of the design. The unconnected ports or pins of each cell in **cell_list** are removed from the cell, its reference, and its subdesign simultaneously so that the current design links after applying **remove_unconnected_ports**.

After a port is removed, any unused nets in the top design and in the design from where the port was removed are cleaned up.

Unless you specify the **-blast_buses** option, bused ports are removed only if all ports of the bus are unconnected.

Note: If your design contains references to subdesigns, there is a possibility of encountering link errors when using **remove_unconnected_ports**. For example, consider the situation where two designs, A and B, both reference subdesign C. Executing **remove_unconnected_ports** on design A might remove ports from subdesign C, so that design B then fails to link. The same situation occurs when design A is read in, **remove_unconnected_ports** is applied, then the original version of design A is read in again. One workaround is to ungroup one of the designs completely so that it does not have references to subdesigns.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all unconnected ports that exist in the current design.

```
prompt> remove_unconnected_ports find( -hierarchy cell, "")
Removing port 'CI' from design 'uport1_DW01_addsub_5_0'
Removing port 'CO' from design 'uport1_DW01_addsub_5_0'
1
```

The following example removes all unconnected ports that exist in the current design, any bus that has an unconnected port is deleted, and the unconnected ports of the bus are removed.

```
prompt> remove_unconnected_ports\
-blast_buses find( -hierarchy cell, "")
Removing port 'A_4' from design 'uport1_DW01_addsub_5_0'
Removing port 'A_3' from design 'uport1_DW01_addsub_5_0'
Removing port 'B_4' from design 'uport1_DW01_addsub_5_0'
Removing port 'B_3' from design 'uport1_DW01_addsub_5_0'
Removing port 'CI' from design 'uport1_DW01_addsub_5_0'
Removing port 'SUM_4' from design 'uport1_DW01_addsub_5_0'
Removing port 'SUM_3' from design 'uport1_DW01_addsub_5_0'
Removing port 'CO' from design 'uport1_DW01_addsub_5_0'
1
```

SEE ALSO

`remove_port(2)`

remove_user_shape

Remove objects of user shapes. The objects can be specified by a collection or by name.

SYNTAX

```
status_value remove_user_shape
[-verbose]
user_shapes
```

ARGUMENTS

-verbose

If this option not specified, suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

user_shapes

Specifies a nonempty collection handles to user shapes or the name of the user shape.

DESCRIPTION

This command removes all specified user shapes, and then returns 1 if successful, or 0 if it fails.

If invalid handles occur in the input handle collection, the command line interpreter removes them from the collection and invokes the `remove_user_shape` command with the updated collection.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes user shapes.

```
> set a [get_user_shape]
{"RECTANGLE#6682", "TRAPEZOID#7196", "POLYGON#6683"}
> remove_user_shape $a
1
```

SEE ALSO

```
create_user_shape(2)
get_user_shapes(2)
remove_net_shape(2)
```

remove_via

Removes vias.

SYNTAX

```
status_value remove_via
[-verbose]
vias
```

Data Types

vias list

ARGUMENTS

```
-verbose
      Prints additional messages.

vias
      Specifies a nonempty collection of handles to vias.
```

DESCRIPTION

This command removes all specified vias. If the input collection is empty, the command returns 0 to indicate failure. If any invalid handles occur in the input handle collection, the command line interpreter removes them from the collection and invokes the **remove_via** command with the updated collection.

This command returns 1 if successful, or 0 if it fails.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the vias specified by the **get_vias** command:

```
prompt> remove_via [get_vias -of_objects n300
1
```

SEE ALSO

```

remove_via
1560

remove_voltage_area

Removes voltage areas from the current design.

SYNTAX

```
int remove_voltage_area
[-verbose]
-all | patterns
```

Data Types

patterns list

ARGUMENTS

-verbose
Prints additional messages.

-all
Removes all voltage areas in the current design.

patterns
Specifies the voltage areas. The patterns can be a collection handle of voltages or names of patterns. You can use the *get_voltage_areas* command. to specify objects.

DESCRIPTION

This command removes voltage areas from the design.

When a voltage area is removed, all its hierarchical cells are also deassociated with the voltage area. After one hierarchical cell is deassociated, its all leaf child cells will be reassociated with the its nearest ascent's voltage area, if any. If none of its ascents is associated with any voltage area, or it doesn't have any ascents, its all leaf child cells will be free.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes voltage areas whose names begin with *tap*.

```
prompt> remove_voltage_area tap*
```

SEE ALSO

create_voltage_area(2)

```
get_voltage_areas(2)
report_voltage_area(2)
update_voltage_area(2)
```

```
remove_voltage_area
1562
```

remove_vt_filler_rule

removes multiple threshold voltage filler cell insertion rules.

SYNTAX

```
integer remove_vt_filler_rule
      -threshold_voltage
```

ARGUMENTS

-threshold_voltage *vt_type_1 vt_type_2*

Specifies the threshold voltage types of the rule to be removed.

DESCRIPTION

Use this command to remove multiple threshold voltage filler rules of the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example will remove threshold voltage rule for "vt_type_A" "vt_type_B"

```
prompt> remove_vt_filler_rule -threshold_voltage "vt_type_A" "vt_type_B"
```

SEE ALSO

```
insert_stdcell_filler(2)

set_left_right_filler_rule(2)
set_vt_filler_rule(2)
report_vt_filler_rule(2)
```

remove_well_filler

Deletes all well fillers in a specified layer.

SYNTAX

```
int remove_well_filler  
-layer  
[-core_only]
```

ARGUMENTS

```
-layer {layer_name}  
        Specifies layer from which well fillers are to be removed. This can be any  
        valid  
  
-core_only  
        Specifies that the core area is to be considered as the bounding-box for  
        purging the well fillers.
```

DESCRIPTION

The *remove_well_filler* command removes well fillers from a specified layer. Well fillers are inserted in the design after placement through *insert_well_filler* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes well fillers from layer NWELL:
prompt> remove_well_filler -layer NWELL

SEE ALSO

```
insert_diode(2)  
insert_ng_filler(2)  
insert_pad_filler(2)  
insert_stdcell_filler(2)  
insert_well_filler(2)
```

remove_xtalk_prop

remove aggressor/victim list properties

SYNTAX

status **remove_xtalk_prop**

DESCRIPTION

This command removes aggressor/victim list properties.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example will remove the net xtalk info.

```
prompt> remove_xtalk_prop
```

SEE ALSO

remove_zrt_filler_with_violation

Deletes filler cells that have Zroute routing violations.

SYNTAX

```
status remove_zrt_filler_with_violation
[-name cell_name]
```

Data Types

cell_name list

ARGUMENTS

-name *cell_name*

Specifies the pattern of the cell instance names.

If you do not specify this option (if you specify "*" or ".*"), the pattern defaults to ".*xofiller.*". If you use this default pattern, all instance names that have the "*xofiller*" substring in them, including hierarchical names, are considered for removal. If cells to be deleted match the name pattern, but are not filler cells, an information message alerts you about the first 50 cells that are deleted.

DESCRIPTION

This command deletes all filler cells that have Zroute routing design rule violations. Filler cells are standard cells without any connections to signal nets.

This command is useful when you add filler cells after performing signal routing with Zroute.

Filler cells that have power or ground (PG) pins that are not assigned to a PG net are deleted if they touch other PG objects, such as rails or pins assigned to a PG net. Therefore, you should connect these pins to PG nets before running the **remove_zrt_filler_with_violation** command. For information about connecting pins to PG nets, see the man pages for the **connect_pg_nets** or **insert_stdcell_filler** commands.

Internal violations in filler cells (between objects of the same cell) are not considered for filler cell removal. If the tool detects this type of violation, a warning is issued once per individual cell.

The tool outputs an information message about the violation type that caused the deletion for the first 50 deleted cells. If there are multiple violations for the same cell, only one of them is listed.

It is a known limitation of the **remove_zrt_filler_with_violation** command that when filler cells are removed, new violations might be introduced with neighboring filler cells. Therefore, you should run the **remove_zrt_filler_with_violation** command multiple times until no more filler cells are removed. In other words, until the informative message "Deleted 0 cell instances" is displayed.

EXAMPLES

The following example removes all filler cells with the prefix "xofiller" that have Zroute routing violations.

```
prompt> remove_zrt_filler_withViolation -name "xofiller.*"
```

SEE ALSO

`insert_stdcell_filler(2)`

rename

Rename or delete a command.

SYNTAX

```
string rename
oldName newName
string oldName
```

ARGUMENTS

DESCRIPTION

Rename the command that used to be called *oldName* so that it is now called *newName*. If *newName* is an empty string then *oldName* is deleted. *oldName* and *newName* may include namespace qualifiers (names of containing namespaces). If a command is renamed into a different namespace, future invocations of it will execute in the new namespace. The **rename** command returns an empty string as result.

Note that the **rename** command cannot be used on permanent procedures. Depending on the application, it can be used on all basic builtin commands. In some cases, the application will allow all commands to be renamed.

WARNING: **rename** can have serious consequences if not used correctly. When using **rename** on anything other than a user-defined Tcl procedure, you will be warned. The **rename** command is intended as a means to wrap other commands: that is, the command is replaced by a Tcl procedure which calls the original. Parts of the application are written as Tcl procedures, and these procedures can use any command. Commands like **puts**, **echo**, **open**, **close**, **source** and **many others are often used within the application. Use rename with extreme care and at your own risk.** Consider using **alias**, Tcl procedures, or a private namespace before using **rename**.

EXAMPLES

This example renames `my_proc` to `my_proc2`:

```
prompt> proc my_proc {} {echo "Hello"}
prompt> rename my_proc my_proc2
prompt> my_proc2
Hello
prompt> my_proc
Error: unknown command 'my_proc' (CMD-005).
```

SEE ALSO

`define_proc_attributes(2)`

rename_mw_cel

Renames a Milkyway design.

SYNTAX

```
int rename_mw_cel
old_name
new_name
[-all_version]
```

Data Types

<i>old_name</i>	string
<i>new_name</i>	string

ARGUMENTS

old_name

Specifies the name of the Milkyway design to be renamed. The value of *old_name* should contain only the base name of an mw_cel. It cannot have a view name and version.

new_name

Specifies the new name of the Milkyway design. The *new_name* should not match the name of any Milkyway designs referenced by a instance in the *old_name* option. The *new_name* should contain only the base name of a mw_cel. It cannot have a view name and version.

-all_version

Indicates to rename all versions of the Milkyway design. By default, this command renames the newest version of the Milkyway design specified by *old_name* to *new_name*.

DESCRIPTION

This command renames a Milkyway design. By default, it renames the newest version of the Milkyway design specified by *old_name* to *new_name*. It renames only the latest version of all views of an mw_cel, unless you use the **-all_version** option; then it renames all versions of all views of an mw_cel.

Each Milkyway design name must be unique within the library containing that Milkyway design. An error occurs if the *new_name* you specify matches the name of a Milkyway design that is referenced by a instance in *old_name*, as this will cause a recursive reference to exist.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example renames a Milkyway design named *test* to *bill*:

```
prompt> get_mw_cels *
{"top", "test"}
prompt> rename_mw_cel test bill
1
prompt> get_mw_cels *
{"top", "bill"}
```

SEE ALSO

copy_mw_cel(2)
create_mw_cel(2)
current_mw_cel(2)
get_mw_cels(2)
mw_cel_collection(2)
open_mw_cel(2)
remove_mw_cel(2)
```

rename_mw_lib

Renames a Milkyway library.

SYNTAX

```
status_value rename_mw_lib
-from lib_name
-to lib_name
```

Data Types

lib_name string

ARGUMENTS

```
-from lib_name
      Specifies the name of the Milkyway library that is to be renamed. The
      specified Milkyway library must not be open in current session.

-to lib_name
      Specifies the new name of the Milkyway library.
```

DESCRIPTION

This command renames a Milkyway library.

If this library is a reference library of another main library, you may need to use the **set_mw_lib_reference** command to update reference library information in the main library.

A status indicating success or failure is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example changes the name of the library from *access05* to *access06*:

```
prompt> rename_mw_lib -from access05 -to access06
```

SEE ALSO

copy_mw_lib(2)

replace_power_switch

Replaces the reference cells of the specified header or footer cell instances with the specified reference cell and performs IR drop analysis.

SYNTAX

```
status_value replace_power_switch
-cells {instances}
-lib_cell {lib_cell_or_power_switch}
[-virtual_pg_net virtual_net]
[-real_pg_net real_net]
[-no_analyze_power]
```

Data Types

<i>instances</i>	collection or list
<i>lib_cell_or_power_switch</i>	collection or list of one item
<i>virtual_net</i>	collection or list of one item
<i>real_net</i>	collection or list of one item

ARGUMENTS

-cells {*instances*}

Specifies the header or footer instances to be replaced.

-lib_cell {*lib_cell_or_power_switch*}

Specifies the header or footer library cell to be used for replacement. The *lib_cell_or_power_switch* argument can contain only one header or footer library cell. The specified library cell must be a multithreshold CMOS (MTCMOS) cell and must be functionally equivalent to the cells being replaced. Use lib cell for non-United Power Format (non-UPF) mode, and use power switch for UPF mode.

-virtual_pg_net *virtual_net*

Specifies a virtual power or ground net on which to perform IR drop analysis. Virtual power nets connect to the virtual power pins of the MTCMOS cells. The virtual power net can be powered down by the MTCMOS header or footer cells to reduce leakage power.

Under UPF mode, this option is optional. The default is to get the output supply net from the output port of the power switch.

-real_pg_net *real_net*

Specifies a real power or ground net to perform power network analysis. Real power nets connect to the real power pins of MTCMOS cells. The real power net is not powered down.

Under UPF mode, this option is optional. The default is to get the input supply net connectivity from the input port of the power switch.

-no_analyze_power

Skips the analyzing of power networks.

DESCRIPTION

This command replaces existing header or footer cells with the specified library cell and performs IR drop analysis with the power network analysis engine. It generates an IR drop report before and after cell replacement.

Header and footer cells typically contain low leakage P/N transistors to reduce the leakage current during power down mode.

You can use this command at the MTCMOS power planning stage to optimize the IR drop of the design. Use it when the MTCMOS cells and power network already physically exist in the design.

The specified instances to be replaced should be connected to the specified virtual and real power and ground nets. The tool attempts to adjust the location of the incoming cells so that the metal connections of the pins are preserved. The **replace_power_switch** command does not perform routing.

It assumes that the cells to be replaced are functionally equivalent, have the same cell height, and that the locations of the pins are compatible. Otherwise, the replacement can result in power and ground connections that are physically broken and impossible to realize. This can cause incorrect IR drop analysis.

If the replacement cell is larger than the original cell, the tool does not perform legalization. You must perform legalization later if the design from this command is to be accepted.

PREREQUISITES

Before executing this command, perform the following tasks:

1. Define the power-on resistance of the header or footer cell by using the **set_attribute** command to set the **mtcmos_resistance** attribute.
2. Specify the metal layer for the power pins by using the **set_attribute** command to set the **mtcmos_pin_layers** attribute.
3. Define the power pad or virtual power pad by using the **create_fp_virtual_pad** command.
4. Verify that the virtual and real power and ground nets of all standard cells have been properly connected logically in the netlist. Use the **derive_pg_connection** command if necessary. A standard cell to be powered down should connect to a virtual power or ground net. A standard cell that always stays on should be connected to a real power or ground net.
5. Use **set_mtcmos_pna_strategy** to define power network analysis related options.

The steps described above are necessary for the power network analysis engine to compute the IR drop.

EXAMPLES

The following example replaces the reference cell of the instances named *HEAD_8* with the HEAD_16 library cell. The power nets to be analyzed are VIRTUAL_VDD and VDD. The command generates IR drop reports before and after replacement.

```
prompt> replace_power_switch\  
-cells [get_cells "*HEAD_8*"]\  
-lib_cell HEAD_16 -virtual_pg_net VIRTUAL_VDD\  
-real_pg_net VDD
```

The following example is for under UPF mode, so it uses PS_A for the library cell.

```
prompt> replace_power_switch\  
-cells [get_cells "*HEAD_8*"]\  
-lib_cell PS_A -virtual_pg_net VIRTUAL_VDD\  
-real_pg_net VDD
```

SEE ALSO

```

report_adjusted_endpoints

Gives a report of the adjusted endpoints in feasibility mode.

SYNTAX

```
int report_adjusted_endpoints
[-zero_path]
[-zero_wire_load]
[-io]
[-slack_threshold]
[-all]
[-verbose]
[-scenarios {scenario_name1, scenario_name2, ...}]
```

ARGUMENTS

-zero_path

This option reports only on endpoints that have been adjusted for zero_path violations, where zero_path margins have been added to the endpoint required times.

-zero_wire_load

This option reports on only endpoints that have been adjusted for zero_wire_load violations, where zero_wire_load margins have been added to the endpoint required times.

-io

This option reports on only endpoints that have been adjusted due to I/O margins that were added to the endpoint required times.

-slack_threshold

This option reports only on endpoints that have been adjusted for slack_threshold, where slack threshold margins have been added to the endpoint required times.

-all

This option reports on all adjusted endpoints irrespective of the reasons for the adjustment.

-verbose

This option controls the amount of information that is printed in the report. The default is non-verbose mode, which gives a summary of the adjustments for the given scenario or the current scenario otherwise. If this option is specified, the report will list the individual adjusted endpoints and the reasons given.

-scenarios {scenario_name1, scenario_name2, ...}

This option reports only on adjusted endpoints of the given scenarios. The default is to return reports only on adjusted endpoints of the current scenarios.

DESCRIPTION

Feasibility mode enables constraint relaxation for unachievable endpoints for reporting commands and the **place_opt** command. During feasibility mode, unachievable endpoints are identified and required time on the unachievable endpoints are relaxed based on the unachievable timing portion. Endpoints with Zero path violation and Zero wire load violations are considered unachievable endpoints.

This command allows you to obtain information about the endpoints that have been adjusted for the given specific reasons and scenarios. The default issues reports on the adjusted endpoints of the current scenario.

EXAMPLES

The following examples show how to use the **report_adjusted_endpoints** command.

```
prompt> report_adjusted_endpoints -zero_path -scenario s1
Scenario s1
There are a total of 3 endpoints adjusted.
```

```
prompt> report_adjusted_endpoints -zero_path -scenario s1 -verbose
Scenario s1
Top/B_A/B/C1/a  (zero path)
Top/B_A/C2/b  (zero path)
Top/C_A/C2/b  (zero path)
There are a total of 3 endpoints adjusted.
```

SEE ALSO

```
place_opt(2)
set_feasibility_options(2)
report_feasibility_options(2)
```

report_ahfs_options

Writes a report about the automatic high-fanout synthesis (AHFS) options.

SYNTAX

```
integer report_ahfs_options
```

ARGUMENTS

The **report_ahfs_options** command has no arguments.

DESCRIPTION

This command reports all of the options set for running automatic high-fanout synthesis (AHFS). See the **set_ahfs_options** command man page for the default values of the options and a description of how each option can control the AHFS flow.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the current AHFS options:

```
prompt> report_ahfs_options

Report AHFS options:
*****
AHFS options for the design:
    High-fanout(HF) threshold: 50
    Medium-fanout(MF) threshold: -1
    Remove effort: medium
    Enable port punching: ON
    Default Reference : buffer_1
1
```

SEE ALSO

set_ahfs_options(2)

report_annotated_check

Displays all annotated timing checks on the current design.

SYNTAX

```
int report_annotated_check  
[-nosplit]
```

ARGUMENTS

-nosplit

Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column. **-nosplit** prevents line splitting and facilitates writing software to extract information from the report output.

DESCRIPTION

Lists all annotated timing checks in the current design. Pin-to-pin timing checks reported are setup and hold.

To list annotated delays, use **report_annotated_delay**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following is an example of an annotated report.

```
prompt> report_annotated_check
```

```
*****  
Report : annotated_check  
Design : counter  
Version: v3.1  
Date   : Tue Apr 14 19:42:25 1992  
*****
```

Cell Name	From	To	Rise	Fall	Timing Check
U1	c	d	-0.20	-0.20	hold
U1	c	d	2.20	2.20	setup

SEE ALSO

`remove_annotated_check(2)`
`report_annotated_delay(2)`
`reset_design(2)`
`set_annotated_check(2)`

report_annotated_delay

Displays all annotated delays on cells and nets of the current design.

SYNTAX

```
int report_annotated_delay
[-cell] [-net] [-nosplit] [-summary]
```

ARGUMENTS

-cell

Reports all data annotated on cells. By default, both cell- and net-annotated data are reported.

-net

Reports all data annotated on nets. By default, both cell- and net-annotated data are reported.

-nosplit

Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The **-nosplit** option prevents line splitting and facilitates writing software to extract information from the report output.

-summary

Reports the total number of cell/net delay arcs and how many of them have got annotation. An arc will be considered as annotated only if all the four delay values (rise, fall, min, max) are present on it.

DESCRIPTION

report_annotated_delay lists all annotated data on cells and nets in the current design. The cell-annotated data reported are the pin-to-pin delays. The net-annotated data reported are pin-to-pin delays, net capacitances, and net resistances. Note that the delay values reported are the resulting cell and net delays used in **report_timing** and might not be your annotated values if delays were annotated using the **-load_delay net** option of the **read_sdf** or **set_annotated_delay** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following is an example of an annotated report.

```
prompt> report_annotated_delay
```

```
*****
```

Report : annotated -cell

Design : counter

Version: v3.0

Date : Tue Apr 14 19:42:25 1992

```
*****
```

Cell Name	From	To	Rise	Fall
CO	A	Z	100.00	100.00

```
*****
```

Report : annotated -net

Design : counter

Version: v3.0

Date : Tue Apr 14 19:42:25 1992

```
*****
```

Net Name	From	To	Rise	Fall	Load	Res.
h	ffc/QN	w/A	200.00	200.00	50.00	200.00
h	ffc/QN	m/B	200.00	200.00	50.00	200.00
h	ffc/QN	r/B			50.00	200.00
m	m/Z	CO/A	200.00	200.00	40.00	100.00

SEE ALSO

```
read_sdf(2)
set_annotated_delay(2)
remove_annotated_delay(2)
reset_design(2)
```

report_annotated_transition

Displays annotated transitions on all pins of the current design.

SYNTAX

```
int report_annotated_transition  
-nosplit
```

ARGUMENTS

-nosplit
Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_annotated_transition** command lists annotated transition times at every pin in the current design.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following is an example of an annotated transition time report.

```
prompt> report_annotated_transition  
  
report_annotated_transition  
  
Pin Name      max_rise      max_fall      min_rise      min_fall  
-----  
U0/A          10.00        -            -            17.00  
U1/A          -            -            -            9.10  
U1/Z          -            -            -            7.00  
1
```

SEE ALSO

```
remove_annotated_transition(2)  
reset_design(2)  
set_annotated_transition(2)
```

report_antenna_ratio

Runs the antenna checker in the router and dumps a detailed report of antenna violations into the log file.

SYNTAX

```
integer report_antenna_ratio
```

ARGUMENTS

The **report_antenna_ratio** command has no arguments.

DESCRIPTION

The **report_antenna_ratio** command runs the antenna checker in the router of an open cell and dumps a detailed report of antenna violations into the log file.

No options are provided.

The log file should provide reports similar to the following:

```
Antenna Violation for Net f1mod_0/l1extflops_0/n2598 Port [f1mod_0/l1extflops_0/U647,I] GateArea = 0.19 Layer [METAL2] sw-ratio = 559.95 (over 395) Antenna Violation for Net f1mod_0/l1extflops_0/io_PB1_Dout_Q1378_57_ Port [f1mod_0/l1extflops_0/U641,I] GateArea = 0.19 Layer [METAL4] sw-ratio = 1455.07 (over 395) Antenna Violation for Net f1mod_0/l1extflops_0/n2671 Port [f1mod_0/l1extflops_0/U639,I] GateArea = 0.19 Layer [METAL4] sw-ratio = 515.66 (over 395) 'Top-layer Antenna' Violation for Net f1mod_0/s1extflops_0/n611 Total GateArea = 0.36 Layer [METAL5] sw-ratio = 3426.94 (over 2670.56)
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
report_antenna_ratio
```

report_antenna_rules

Reports all of the antenna rules stored in the library.

SYNTAX

```
status_value report_antenna_rules
[mw_lib]
[-output file_name]
```

Data Types

<i>mw_lib</i>	list
<i>file_name</i>	string

ARGUMENTS

mw_lib

Specifies the Milkyway library to be updated. The value of *mw_lib* can be a library name or a one-element collection of a library. The *mw_lib* option is optional. The default is to use the current Milkyway library.

-output *file_name*
The name of a specified output file.

DESCRIPTION

This command reports all of the antenna rules stored in the library to a file or to the window. The command returns a status indicating success or failure.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> report_antenna_rules
```

SEE ALSO

```
define_antenna_layer_ratio_scale(2)
define_antenna_layer_rule(2)
define_antenna_rule(2)
remove_antenna_rules(2)
```

report_area

Displays area information for the current design or instance.

SYNTAX

```
integer report_area
[-nosplit]
[-physical]
[-hierarchy]
```

ARGUMENTS

-nosplit

Prevents line-splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-physical

Reports the size of the core area and the aspect ratio of the design.

-hierarchy

Reports the area used by cells across the design hierarchy. Reports the absolute value and the percentage of area consumed by each of the cells across the hierarchy. This option also reports the details of area contribution by combinational, non-combinational, and black box cells.

DESCRIPTION

The **report_area** command lists current instance or current design statistics including combinational, non-combinational, and total area. If you set the **current_instance** command, the report is generated for the design of that instance. Otherwise the report is generated for the current design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example generates an area report:

```
prompt> report_area
*****
Report : area
Design : CONTROL
Version: v2.0
```

```
Date      : Fri Mar 16 14:09:12 1991
*****
Library(s) Used:
```

```
tech_lib (File: /usr/synopsys/libraries/tech_lib.db)
```

```
Number of ports:          33
Number of nets:           50
Number of cells:          22
Number of references:     8

Combinational area:       110.00
Noncombinational area:    64.00
Net Interconnect area:    0.00

Total area:               174.00
```

```
Information: This design contains unmapped logic. (RPT-7)
Information: This design contains black box (unknown) components. (RPT-8)
```

The following example generates an area report for a hierarchical design using the **-hierarchy** option:

```
prompt> report_area -hierarchy
```

```
*****
Report : area
Design : top
Version: Y-2006.06
Date   : Mon Dec 12 04:25:09 2005

Total			16.0000	168.0000	0.0000	

SEE ALSO

`report_design(2)`
`set_max_area(2)`

report_attribute

Reports the attributes on one or more objects.

SYNTAX

```
string report_attribute
[-application]
[-class class_name]
[-quiet]
[object_list]
```

Data Types

<i>class_name</i>	string
<i>object_list</i>	list

ARGUMENTS

```
-application
    Lists application attributes and user-defined attributes.

-class class_name
    Specifies the class name for the object specified in object_list, if the
    element of object_list is a name. Valid classes are design, port, cell, net,
    and so forth.

-quiet
    Indicates that all error and warning messages are not to be reported.

object_list
    Specifies a list of objects to report. Each element in the list is either a
    collection or a pattern that is combined with the class_name to find the
    objects.
```

DESCRIPTION

The **report_attribute** command generates a report of attributes on the specified objects. By default, only user-defined attributes display.

Using the **-application** option adds application attributes to the report.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the attributes on a specified net object:

```

prompt> report_attribute [get_nets clk2] -app

*****
Report : Attribute
LIBRARY: astro_tcl
DESIGN : top
Date   : Wed Sep  8 10:26:17 2004
*****

Design  Object  Type      Attribute Name    Value
-----
top    clk2    string    base_name        clk2
top    clk2    boolean   dont_touch       false
top    clk2    boolean   ideal_net        false
top    clk2    boolean   is_physical     false
top    clk2    boolean   is_tie_high_net false
top    clk2    boolean   is_tie_low_net  false
top    clk2    string    net_type        Clock
top    clk2    int       num_overall_pins 2
top    clk2    int       num_pins        2
top    clk2    string    owner          top
top    clk2    string    route_length    {{METAL3 28.000} {METAL2 8.110}}
top    clk2    int       cell_id         3
top    clk2    string    full_name       clk2
top    clk2    string    mw_name         clk2
top    clk2    string    name           clk2
top    clk2    int       number_of_wires 8
top    clk2    string    object_class    net
top    clk2    int       object_id       2816
-----
```

The following example limits the reporting to user-defined attributes only:

```

prompt> define_user_attribute -class net attr_s -type string
Info:User-defined attribute 'attr_s' on class 'net'.
1
prompt> set_attribute -class net clk2 attr_s hello
Info:Setting attribute 'attr_s' on net 'clk2'.
{"clk2"}
prompt> report_attribute -class net clk2

*****

report_bounds

Reports bounds in the design.

SYNTAX

```
int report_bounds  
-all | bound | -name name_list
```

Data Types

<i>bound</i>	list
<i>name_list</i>	list

ARGUMENTS

-all
Specifies to report all bounds that were created with `create_bounds`. Bounds from an input PDEF file will not be reported with this command.

bound
Specify the bound objects. The bound objects can be specified by the command `get_bounds`.

-name *name_list*
Reports bounds with the specified names.

DESCRIPTION

The `report_bounds` command generates reports on the user-specified bounds constraints in the design, as specified by the `create_bounds` command. If `-all` is used, all bounds in the design created by `create_bounds` will be reported. Bounds created by an input PDEF file will not be reported. If a list of bound names is specified, those bounds will be reported. This report includes the bound name, the type of the bound, the effort level, and the list of cells that belong to the bound.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports bounds of names "foo_1" and "foo_2".

```
prompt> report_bounds -name {foo_1 foo_2}  
Report bounds:  
*****  
Bound Name: foo_1, type: high effort auto group bound  
Cells: a b c d  
Bound Name: foo_2, type: soft moving bound {10 20 30 40}
```

```
Cells: e f
*****
```

SEE ALSO

```
create_placement(2)
create_bounds(2)
update_bounds(2)
set_cell_location(2)
remove_bounds(2)
get_bounds(2)
```

report_buffer_tree

Reports the buffer tree and its level information at the given driver pin.

SYNTAX

```
status report_buffer_tree
[-from start_point_list | -net net_list]
[-break_points]
[-depth max_depth]
[-connections]
[-hierarchy]
[-physical]
[-nosplit]
```

Data Types

<i>start_point_list</i>	list
<i>net_list</i>	list
<i>max_depth</i>	int

ARGUMENTS

-from *start_point_list*
Specifies the starting point of the buffer tree. The starting point is defined as level 0 of the tree. The *start_point_list* must contain only pins or ports.

-net *net_list*
Specifies a net as the starting point of the buffer tree. The *net_list* must contain only nets.

-break_points
Reports the hierarchical pins on the nets that are break points. There are several reasons that a hierarchical pin can be a break point. See Man Page for message HFS-720. AHFS will preserve the break point and build buffer trees before and after the break point, if needed.
This option also reports connection class conflicts on nets that connect pins with non-intersecting connections class attributes from the library. The reported nets have at least two pins with no common classes. Pins with the 'universal' class are not reported, as they can connect to any other pin.

-depth *max_depth*
Reports only the *max_depth* levels of buffers in the tree. The default is to report the buffer tree until a real load or hierarchical boundary is reached.

-connections
Shows the net connections in the report. By default, the net connections are not shown.

-hierarchy
Shows the buffer tree across the hierarchy. By default, the report terminates at hierarchical boundaries.

```
-physical  
    Displays the location for each pin, with the coordinates in microns.  
  
-nosplit  
    Prevents linesplitting, making it easier to write scripts to extract  
    information from the report output. By default, the design information is  
    listed in fixed-width columns. If the information in a given field exceeds  
    the column width, the next field begins on a new line, starting in the correct  
    column.
```

DESCRIPTION

The **report_buffer_tree** command reports a buffer tree at the given driver pins or driver nets. It reports the full name of the driver pin (which includes the name of the cell), the name of the library cell, and the level of the driver relative to the starting point. The starting point is defined as level 0 of the tree.

Reporting terminates at the non-buffer pins, hierarchical boundaries (except when the **-hierarchy** option is used), or when the level reported exceeds the value specified by *max_depth*.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to report a buffer tree:

```
prompt> report_buffer_tree -from cell1/0
```

The following example shows how to report a buffer tree with net connections:

```
prompt> report_buffer_tree -connections -from cell1/0
```

SEE ALSO

```
all_fanout(2)  
create_buffer_tree(2)  
remove_buffer_tree(2)  
report_constraint(2)  
report_hierarchy(2)  
report_net_fanout(2)
```

report_buffer_tree_qor

Displays quality related properties of the buffer trees at the given driver pins.

SYNTAX

```
int report_buffer_tree_qor
[-from list_of_driving_pins_or_nets]
```

Data Types

list_of_driving_pins_or_nets list

ARGUMENTS

```
-from list_of_driving_pins_or_nets
      Specifies the starting points of the buffer trees to be reported.
```

DESCRIPTION

The **report_buffer_tree_qor** command reports quality related properties of the buffer trees at given driver pins or driver nets. The report is presented as a spreadsheet containing the following columns: 1) Number of sinks (non-buffer loads); 2) Number of buffers and inverters; 3) Number of buffer levels; 4) Buffers' area; 5) Number and value of design rule violations - max_tran, max_cap and max_fanout 6) Total negative slack on the sinks; 7) Worst slack among the sinks; 8) Maximum immediate fanout in the tree (max. sub-tree fanout) 9) Name of the driving pin

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to report quality of all buffer trees with number of sinks exceeding 100.

```
prompt> report_buffer_tree_qor \ -from [all_high_fanout -nets -threshold 100
-through]
=====

report_bus

Lists the bused ports and nets in the current instance or in the current design.

SYNTAX

```
integer report_bus
[-nosplit]
```

ARGUMENTS

-nosplit

Prevents line-splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

This command displays information about buses in the current instance or the current design. If the current instance has been set, the report is generated for the design of that instance. Otherwise, the report is generated for the current design.

Buses are indexed in ascending order in the report. If a bus is named in descending order, the numbers in the "Step" column are negative. Bused pins are not listed in the report because the bus commands operate only on design ports (not reference ports).

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command displays bus information on the current design:

```
prompt> report_bus

*****
Report : bus
Design : SUBTRACTOR
Version: v2.0
Date   : Fri Mar 16 14:22:01 1991
*****
Bussed Port    Dir      From     To      Step    Width   Type
-----
A             in       0        3        1        4    array
B             in       0        3        1        4    array
DIFF          out      0        3        1        4    array
```

Bussed Net	From	To	Step	Width	Type
A	0	3	1	4	array
B	0	3	1	4	array
DIFF	0	3	1	4	array

SEE ALSO

`remove_bus(2)`

report_case_analysis

Reports case analysis on ports or pins.

SYNTAX

```
string report_case_analysis
[-all] [-nosplit]
```

ARGUMENTS

-all

Specifies to report the built-in constant pins of the design that are considered for startpoints of constant propagation. Propagation of logic constants is only done if the **set_case_analysis** command was executed, or the variable **case_analysis_with_logic_constants** or **disable_case_analysis** is set to true.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_case_analysis** command reports case analysis entries specified with the **set_case_analysis** command. The report lists all pins and ports on which case analysis is specified. The list does not report where the logic constant values are propagated.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example specifies that pins U1/U2/A and U1/U3/CI are set to a constant of logic 1.

```
prompt> set_case_analysis 1 {U1/U2/A U1/U3/CI}
prompt> report_case_analysis

*****
Report : case_analysis
Design : middle
Version: 1997.01-development
Date   : Mon Jul 22 17:04:17 1996
*****
```

Pin name	User case analysis value
<hr/>	
U1/U2/A	1
U1/U3/CI	1

SEE ALSO

`remove_case_analysis(2)`
`set_case_analysis(2)`

report_cbt_options

Reports options used by the **create_buffer_tree** command.

SYNTAX

```
int report_cbt_options
```

ARGUMENTS

The **report_cbt_options** command has no arguments.

DESCRIPTION

The **report_cbt_options** command reports options used by the **create_buffer_tree** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

SEE ALSO

```
create_buffer_tree(2)
set_cbt_options(2)
```

report_cell

Displays information about cells in the current instance or in the current design.

SYNTAX

```
status report_cell
[-nosplit]
[-connections]
[-verbose]
[-physical]
[-only_physical]
[-significant_digits digits]
[cell_list]
```

Data Types

<i>digits</i>	integer
<i>cell_list</i>	list

ARGUMENTS

-nosplit
Prevents line-splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-connections
Displays all pins of the cell and the connected nets.

-verbose
Displays verbose connection information. For each input pin, the tool displays the net and the driver pins on that net. For each output pin, the tool displays the net and the load pins on that net.

-physical
Reports the orientation and location of the cell.

-only_physical
Reports information for physical only cells.

-significant_digits *digits*
Specifies the number of digits to the right of the decimal point that are reported. Allowed values are 0 through 13 and the default is 6. Using this option overrides the value set by the **report_default_significant_digits** variable.

cell_list
Specifies a list of cells and instances to show in the report. If not specified, all cells in the current instance are listed.

DESCRIPTION

This command displays information and statistics about cells in the current instance or current design. If *current_instance* is set, the report is generated for the design of that instance; otherwise the report is generated for the current design.

Parameterized cells are attributed by the letter *p* and contain parameters that control aspects of the designs they instantiate. The actual values of a cell's parameters appear at the bottom of the report.

Control logic cells are designated as type *c* in the report generated by **report_cell**. Use this information to identify control logic cells when using the **group** command. Group control logic cells with the cells that they control.

This command does not display constant cells. To display constant cells, use the following command:

```
get_cell -hier * -filter "@ref_name==**logic_0** || @ref_name==**logic_1**"
```

Use the **-connections** option to list the nets connected to each pin.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following is an example of a cell report:

```
prompt> report_cell
*****
Report : cell
Design : CONTROL
Version: v3.1
Date   : Fri Mar 20 14:09:15 1991
*****

Attributes:
  b - black box (unknown)
  bo - allows boundary optimization
  BO - reference allows boundary optimization
  c - control logic
  d - dont_touch
  D - reference or design is dont_touched
  h - hierarchical
  n - noncombinational
  p - parameterized
  r - removable
  S - synthetic module
  u - contains unmapped logic
```

Cell	Reference	Library	Area	Attributes
IDIN0	NAND2	tech_lib	1.00	
IDIN1	JMPM		0.00	h, u
IDIN2	JMM		0.00	b
IOUT1	NAND2	tech_lib	1.00	
IOUT2	NAND2	tech_lib	1.00	
IOUT3	NAND2	tech_lib	1.00	
R1	NAND3	tech_lib	2.00	
R2	INV	tech_lib	1.00	
U0	MX1P	tech_lib	8.00	n
U1	MX1P	tech_lib	8.00	d, n, 1
U3	MX1P	tech_lib	8.00	d, n
U5	MX1P	tech_lib	8.00	n
U6	MX1P	tech_lib	8.00	n, 2
U7	MX1P	tech_lib	8.00	n
U9	JMM1		0.00	b
U10	JMM1		0.00	b
U15	CTLX		101.00	h
P1	DW01_add		50.00	S, p
<hr/>				
Total 18 cells			206.00	

Flip-Flop Types:

- 1 - Default type MX1, MX1P, MX2, MX2P, MX3, MX3P, MX4, MX4P
- 2 - Exact type LMNO1

HDL Parameters:

P1 - width => 16

The following is an example of a verbose cell connection report for the *t_bar* cell:

```
prompt> report_cell -connections -verbose {t_bar}

*****
Report : cell
    -connections
    -verbose
Design : counter
Version: v3.1
Date   : Fri 1993
*****

Connections for cell 't_bar':
  Reference:      IVA
  Library:       lsi_10k
  Area:          1
  dont_touch:    FALSE

  Input Pins     Net      Net Driver Pins   Driver Pin Type
  -----        -----  -----  -----
  A             t        t/Z                Output Pin (EO)
```

Output Pins	Net	Net Load Pins	Load Pin Type
Z	t_bar	zero/B	Input Pin (OR2)
1			

The following command reports on all of the registers in the current design:

```
prompt> report_cell all_registers()
```

SEE ALSO

```
all_registers(2)
current_design(2)
current_instance(2)
report_design(2)
report_hierarchy(2)
report_net(2)
report_reference(2)
report_default_significant_digits(3)
```

report_cell_physical

Displays information about cells in the current instance or in the current design.

SYNTAX

```
status report_cell_physical
[-connections]
[-verbose]
[cell_list]
```

Data Types

cell_list collection

ARGUMENTS

-connections

Displays all pins of the cell and the connected nets. Connections for power and ground pins are reported separately. For each power and ground pin, the report includes the pin name and the connected nets.

-verbose

Displays verbose connection information. For each input pin, the tool displays the net and the driver pins on that net. For each output pin, the tool displays the net and the load pins on that net.

This option is valid only when you also specify the **-connections** option. Verbose information is not reported for power and ground pins.

cell_list

Specifies the cells and instances to show in the report. If not specified, all cells in the current instance are listed.

DESCRIPTION

This command displays physical information about cells in the current instance or current design. If *current_instance* is set, the report is generated for the design of that instance. Otherwise the report is generated for the current design. By default, the command reports cell instance information, such as cell name, parent name, reference name, library name, site name, bounding box, width, height, location, origin, logical area, physical area, keepout margins, orientation, voltage area name etc,. Use the **-connections** option to list the nets connected to each pin. **-verbose** will give verbose of connectivity information.

EXAMPLES

The following is an example of a cell report:

```
prompt> report_cell_physical U17
*****
```

```

Report  : cell

report_cell_vt_type

prints out voltage threshold type of a cell master or all cell masters of a library.
Voltage threshold type is used for mixed voltage threshold filler cell insertion

SYNTAX

```
integer report_cell_vt_type  
-library library_name | -lib_cell cell_name
```

Data Types

cell_name string

ARGUMENTS

```
-library library_name | -lib_cell cell_name  
Use -library to specify a library name or use -lib_cell to specify a master  
cell name.
```

DESCRIPTION

Use this command to print out vt type string of a master cell or master cells of a library.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example will prints out vt type settings from all master cells of library RefLib1

```
prompt> report_cell_vt_type -library "RefLib1"
```

Below shows the output that says library cell CELL1 in library RefLib1 are set to vt type "vtType2": ## Voltage threshold type of cells in library RefLib1
set_cell_vt_type -lib_cell "CELL1" -vt_type "vtType2"

SEE ALSO

```
set_cell_vt_type(2)  
remove_cell_vt_type(2)  
insert_stdcell_filler(2)  
set_vt_filler_rule(2)
```

report_change_list

Reports the ECO changes after running incremental optimization.

SYNTAX

```
status report_change_list
```

ARGUMENTS

There are no arguments to this command.

DESCRIPTION

The **report_change_list** command reports changes to cells in a design. If there are changes to nets (pin swapping), only new nets that are added can be detected.

To turn off this feature, set the **physopt_change_list** variable to FALSE before running the **physopt -incremental** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **report_change_list** command.

```
prompt> report_change_list

report_change_list
Information: Updating design information... (UID-85)
Status           Cell name          Reference name
-----
deleted         U3196             buf1a3
orientation changed   U21              or2c3
location changed    U6164             or2b2
net changed       U4169             mx2a3
modified         U4546             buf1a6
new              U6387             xor2a6
-----
Total cells changed: 6
```

SEE ALSO

[physopt_change_list\(3\)](#)

report_check_library_options

Reports the values or the status of the options set by the **set_check_library_options** command. The **report_check_library_options** command provides information about options used for checking between logical libraries, options used for checking between physical libraries, and options used for checking between logical libraries and physical libraries.

SYNTAX

```
status report_check_library_options
[-physical]
[-logic_vs_physical]
[-logic]
[-default]
```

ARGUMENTS

-physical

Reports the values or the status of the options set by the **set_check_library_options** command to check between physical libraries.

-logic_vs_physical

Reports the values or the status of the options set by the **set_check_library_options** command to check between logical libraries and physical libraries.

See the **-logic_vs_physical** option in the **set_check_library_options** man page for more information.

-logic

Reports the values or the status of the options set by the **set_check_library_options** command to check between logical libraries.

See the **-logic** option in the **set_check_library_options** man page for more information.

-default

Reports the default values of all the library-checking options. If this option is not specified, the current values of the options are reported.

DESCRIPTION

The **report_check_library_options** command reports the values or the status of the options set by the **set_check_library_options** command. The **report_check_library_options** command provides information about options used for checking between logical libraries, options used for checking between physical libraries, and options used for checking between logical libraries and physical libraries.

Use the **report_check_library_options** command after running **set_check_library_options**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, **report_check_library_options** checks all data for the specified library, test.mw, and then reports the option values:

```
prompt> set_check_library_options -cell_footprint -bus_delimiter
prompt> report_check_library_options -logic_vs_physical
1

Report options for check_library
*****
Check cell area : false
Check cell footprint : true
Check bus delimiter : true
Cell names : (null)
Logic libraries : (null)
Physical libraries : (null)
1
```

SEE ALSO

[check_library\(2\)](#)
[set_check_library_options\(2\)](#)

report_clock

Displays clock-related information on the current design.

SYNTAX

```
status report_clock
[-attributes] [-skew] [-nosplit] [-groups]
[-scenario]
```

ARGUMENTS

-attributes
Provides a list of all the clocks in the current design. The information for each clock includes: source type, signal rise and fall times, and attributes. This report is the default.

-skew
Reports the clock network skew information set on the design by the **set_clock_skew** command. This information includes rise delay, fall delay, plus uncertainty and minus uncertainty of the clock network.

-nosplit
Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column. This option prevents line-splitting and facilitates writing software to extract information from the report output.

-groups
Reports the clock groups information set on the design by the **set_clock_groups** command.

-scenario *scenario_list*
Reports clocks for given list of scenarios of a multiscenario design. Inactive scenarios will be skipped in the report. Each scenario is reported separately. If this option is not given, only the current scenario is reported.

DESCRIPTION

Displays all clock-related information on a design. The report contents are controlled by the options used. If you don't specify an option, the **attributes** report is displayed.

The **report_transitive_fanout -clock_tree** report shows the fanout network of every clock source in the design.

To obtain a list of all clocks in the design, use the **all_clocks** command.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenario** option.

EXAMPLES

The following are examples of clock reports.

```
prompt> report_clock -attributes
```

```

```

report_clock_gating

Reports information about clock gating performed by Power Compiler.

SYNTAX

```
status report_clock_gating
[-no_hier]
[-verbose]
[-gated]
[-ungated]
[-gating_elements]
[-only cell_list]
[-nosplit]
[-physical]
[-multi_stage]
[-style]
[-structure]
[-scenario scenario_list]
```

Data Types

<i>cell_list</i>	list
<i>scenario_list</i>	list

ARGUMENTS

-no_hier

Reports clock-gating information for only the top level of the current design. Without this option, all levels of hierarchy starting from the current design are reported.

-verbose

Reports more detailed information; for example, test information and a list of related registers to the clock-gating cells. By default, this information is not included in the report.

-gated

Reports the names of all gated registers, along with the names of the corresponding clock-gating elements.

-ungated

Reports the names of all ungated registers, along with the unmet clock-gating conditions.

-gating_elements

Reports the names of all clock-gating elements, along with their style, setup and hold times, inputs, and outputs.

-only *cell_list*

Reports information only for the clock-gating cells or gated and ungated registers listed in *cell_list*. By default, information is displayed for all clock-gating cells and ungated and gated registers.

```

-nosplit
    Prevents line-splitting and facilitates writing software to extract
    information from the report output. Most design information is listed in
    fixed-width columns. If information for a field exceeds the column width, the
    next field begins on a new line, starting in the correct column.

-physical
    Reports the physical locations and distance statistics of gating cells and
    gated registers, along with other clock-gating information. This option can
    be used only with the -gating_elements option.

-multi_stage
    Reports multistage clock-gating statistics in the clock-gating summary.

-style
    Reports the clock-gating style of all clock gates in the current design.

-structure
    Produces the Clock Gating Structure Summary and Clock Gating Structure
    Details reports, where the information about clock-gating cells and gated
    registers is classified according to the clock domains to which they belong.
    Additional information about fanout and clock latency set on each clock-
    gating element is also displayed.
    This option can only be combined with the -scenario option.

-scenario scenario_list
    Produces a set of reports for the specified list of scenarios of a
    multiscenario design, when used with the -structure option. To get reports
    for all active scenarios, use "[all_scenarios]" as the scenario_list
    argument.
    If this option is not specified, only the current scenario is reported.

```

DESCRIPTION

The **report_clock_gating** command reports information about clock-gating cells and gated and ungated registers of the current design. To generate the report, **report_clock_gating** uses clock-gating attributes placed on the clock-gating cells by Power Compiler. Any clock gating added by other means (for example, clock gating inferred by or instantiated in the RTL code) lacks these attributes and does not appear in the report.

When the command is issued without options, the report lists the number of clock-gating elements, the number of gated and ungated registers with percentages of the total, and the total number of registers.

When the **-multi_stage** option is specified, the summary also includes multistage clock-gating statistics. These statistics include the number of multistage clock-gating elements (for example, clock gates that have other clock gates in their fanout), the average multistage fanout, the number of gated cells (registers and modules), and the maximum and average number of stages per gated cell. Use one or more of the other options to obtain more detailed information.

When issued with the **-structure** option, the command generates the Clock Gating Structure Summary and Clock Gating Structure Details reports. The Clock Gating

Structure Summary lists, for each clock domain, the total number of registers (gated and ungated), and the number of clock gates and gated elements for each clock gating stage. The Clock Gating Structure Details shows, for each clock domain and each clock gating stage, all clock-gating cells, their respective fanout, clock latency, and gated elements. This option cannot be combined with any other option.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows a report generated when the **report_clock_gating** command is issued with no options: The report shows that out of 6 registers, 4 are gated and 2 are ungated.

```
prompt> report_clock_gating
```

```
*****
Report : clock_gating
Design : low_design
Version: 2000.11
Date   : Thu Jun 21 18:52:39 2001
*****
```

Clock Gating Summary

Number of Clock gating elements	1
Number of Gated registers	4 (66.67%)
Number of Ungated registers	2 (33.33%)
Total number of registers	6

The following example shows a report generated with the **-multi_stage** and **-no_hier** options for a hierarchical multistage clock-gated design. A multistage clock gate is a clock-gating cell that is driving another clock gating cell. The report shows 3 clock-gating elements, 8 gated and no ungated registers at the top level. Two of the 3 clock gates are multistage, and their average fanout is 1.0, indicating that the clock path consists of a chain of 3 clock gates. There is 1 gated module in addition to the 8 gated registers. The 8 registers have 3 stages on their clock path, but the module has only 2, bringing the average number of stages to $((8*3 + 2*1)/9)$.

```
prompt> report_clock_gating -multi_stage -no_hier
```

```

Clock Gating Summary

Number of Clock gating elements	12
Number of Gated registers	92 (90.20%)
Number of Ungated registers	10 (9.80%)
Total number of registers	102

The following example shows a report generated with the **-structure** option for a hierarchical multistage clock gated design with 2 clock domains. In this case the field "Maximum number of stages" is also included in the summary printed at the end.

prompt> **report_clock_gating -structure**

Report : clock_gating
-structure

Clock Gating Summary

Number of Clock gating elements	8
Number of Gated registers	20 (100.00%)
Number of Ungated registers	0 (0.00%)
Maximum number of stages	3
Total number of registers	20

SEE ALSO

report_clock_gating_check

Prints a report of the clock gating checks.

SYNTAX

```
string report_clock_gating_check
[-nosplit]
[-significant_digits digits]
[instance_list]
```

Data Types

<i>digits</i>	integer
<i>instance_list</i>	list

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. By default, most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line in the same column.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are reported. Allowed values are from 0 through 13; the default is 2. Using this option overrides the value set by the variable **report_default_significant_digits**.

instance_list

Specifies designs (all gated clock checks in the specified design), clocks, cells, or pins for which to generate a clock gating report. By default, the report is generated for the current design.

DESCRIPTION

The **report_clock_gating_check** command reports the clock gating checks and the setup hold values. Information displayed about the specified objects include: instance of the cell, enable pin, clock pin, setup/hold time for rise, setup/hold time for fall, user-specified high/low active waveform and clock gating check attributes. The attributes shows from where the clock gating check was original defined:

i	Automatically inferred by Design Compiler
p	Power Compiler inserted the check
l	Defined by the library cell

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example reports user-defined clock gating checks.

```
prompt> set_clock_gating_check -setup 0.27 -hold 0.38
prompt> report_clock_gating_check

*****
Report : clock gating check
Design : top_design
Version: X-2005.09
Date   : Fri Nov 11 14:47:08 2005
*****
```

Cell	Enable	Clock	Rise		Fall		Low/High	Attr
			Setup	Hold	Setup	Hold		
g1/U1	A	B	0.27	0.38	0.27	0.38	High	i
g1/U2	A	B	0.27	0.38	0.27	0.38	Low	i
g1/U3	B	A	0.27	0.38	0.27	0.38	High	i
g1/U4	A	B	0.27	0.38	0.27	0.38	Low	i

Disabled:
None

Attr:
i:auto inferred, p:power compiler inserted, l:library cell defined

In the following example, the first command sets clock gating checks on the design 'test'. The second command sets a clock gating check on cell 'g1/U2' with a non-controlling interval of 'high'. The third command disables the clock gating check on pin 'g1/U3/B'. The fourth command generates a clock gating check report.

The (*) indicates user override of the non-controlling interval for cell 'g1/U2', which is different from what was determined internally. There are no Power Compiler clock gating checks in this design. There is one clock gating check that is disabled on pin 'g1/U3/B'.

```
prompt> set_clock_gating_check -setup 0.33 -hold 0.42 test
prompt> set_clock_gating_check -high -setup 0.21 -hold 0.29 g1/U2
prompt> set_disable_clock_gating_check g1/U3/B
prompt> report_clock_gating_check
```

```
*****
Report : clock gating check
Design : test
Version: X-2005.09
Date   : Fri Nov 11 14:52:18 2005
*****
```

Cell	Enable	Clock	Rise		Fall		Low/High	Attr
			Setup	Hold	Setup	Hold		
<hr/>								
g1/U1	A	B	0.33	0.42	0.33	0.42	High	i
g1/U2	A	B	0.21	0.29	0.21	0.29	High (*)	i
g1/U4	A	B	0.33	0.42	0.33	0.42	Low	i
Disabled:

<i>worst_entries</i>	integer
<i>lower_limit</i>	float
<i>upper_limit</i>	float
<i>slack_upper_limit</i>	float
<i>digits</i>	integer

ARGUMENTS

-type *report_type*

Specifies the type of report to be generated. Allowed values are as follows:

report_clock_timing

1628

- **transition** - specifies a transition time report.
- **latency** - specifies a latency report.
- **skew** - specifies a skew report. You cannot use the **-launch**, **-capture**, **-rise**, **-fall**, **-min**, **-max**, and **-lesser_than** options if you specify a skew report. You can use the **-include_uncertainty_in_skew** option only in a skew, interclock_skew, or summary report.
- **interclock_skew** - specifies an interclock skew report. You cannot use the **-launch**, **-capture**, **-rise**, **-fall**, **-min**, **-max**, and **-lesser_than** options if you specify an interclock skew report. You can use the **-include_uncertainty_in_skew** option only in a skew, interclock_skew, or summary report.
- **summary** - specifies a summary report that shows the worst instances of transition time, latency, and skew over the clock networks or subnetworks of interest. You can use only the **-clock**, **-to_list**, **-from_list**, **-include_uncertainty_in_skew**, **-nosplit**, and **-significant_digits** options if you specify a summary report.

For non-summary reports, report entries are ordered with respect to the specified attribute of interest (transition time, latency, or skew). All skews reported are "local" skews. For an explanation of local skew, see the DESCRIPTION section.

-clock *clock_list*

Specifies a list of clock networks to be used in the report. A subreport is produced for every clock in *clock_list*, unless you additionally specify a *to_list* or a *from_list* that has no network intersection with a given clock. In that case, the tool drops these clocks from the *clock_list* and issues a warning. By default, if you do not specify *clock_list*, all clocks in the design that have associated clock networks are used in the report.

-from_clock *from_clock_list*

Specifies a list of clock networks to be used as from-clocks in the current interclock skew report. This option can be used only in an interclock skew report. The report considers every clock in the *from_clock_list*, unless you additionally specify a *from_list* that has no network intersection with a given clock. In that case, the tool drops these clocks from the *from_clock_list* and issues a warning. By default, if you do not specify a *from_clock_list*, all clocks in the design that have associated clock networks are used as from-clocks in the report.

-to_clock *to_clock_list*

Specifies a list of clock networks to be used as to-clocks in the current interclock skew report. This option can be used only in an interclock skew report. The report considers every clock in the *to_clock_list*, unless you additionally specify a *to_list* that has no network intersection with a given clock. In that case, the tool drops these clocks from the *to_clock_list* and issues a warning. By default, if you do not specify a *to_clock_list*, all clocks in the design that have associated clock networks are used as to-clocks in the report.

-to *to_list*
Specifies the list of sequential clock network pins or ports to consider as to-pins in the current report. If any named pin is not the clock pin of a sequential device (such as a sink pin), the tool replaces that pin with all sequential clock pins in the transitive fanout of the named pin. If there are no sequential clock pins in the pin's transitive fanout, the pin is dropped from the list with a warning message.
For skew reports, the from-to skew sense is defined by the pins in the *from_list* and the *to_list*, respectively. If the *to_list* is not specified, by default all sink pins in the given clock networks are used. Thus, specifying *to_list* reduces the topological scope of the report. For transition time and latency reports, *from_list* and *to_list* are concatenated and treated as a single list. If neither list is specified, *to_list* is assumed to be populated with all sink pins in the given clock networks.

-from *from_list*
Specifies a list of sequential clock network pins or ports to consider as from-pins in the current report. If a named pin is not the clock pin of a sequential device, the tool replaces that pin with all sequential clock pins in the transitive fanout of the named pin. If there are no sequential clock pins in the pin's transitive fanout, the pin is dropped from the list with a warning message.
For skew reports, the from-to skew sense is defined by the pins in the *from_list* and the *to_list*, respectively. If the *from_list* is not specified, by default all sink pins in the given clock networks are used. Specifying the *to_list* reduces the topological scope of the report. For transition time and latency reports, the *from_list* and *to_list* are concatenated and treated as a single list. If neither is specified, the *to_list* is assumed to be populated with all sink pins in the given clock networks.

-setup
Indicates that only the setup data path is to be used in the report, and that the skews, latencies, or transition times reported must correspond to those used by the **report_timing** command in the verification of setup constraints. The **-setup** and **-hold** options are mutually exclusive. If neither option is specified, **-setup** is assumed. This option cannot be used in summary reports.

-launch
Indicates that only pins launching data are to be used in the report, and that latencies or transition times reported must correspond to those used by the **report_timing** command for sequential device clock pins that are launching data. In skew reports, the role is implicit from the from-to sense indicated by the *from_list* and the *to_list*. In all other reports, the **-launch** and **-capture** options are mutually exclusive. If neither option is specified, **-launch** is assumed. This option cannot be used in summary or skew reports.

-rise
Indicates that the active transition is a rising edge for sequential device clock pins in the current report. The **-rise** and **-fall** options are mutually exclusive. If neither option is specified, the active transition at a latch or flip-flop is deduced from the launch or capture role and the behavior of the sequential device itself. This option enables you to answer "what if" questions regarding latency and transition time at sequential device clock pins. This option cannot be used in summary or skew reports.

-min

Specifies that the reports are sorted by minimum latencies or transition times. The **-min** and **-max** options are mutually exclusive. If neither option is specified, the reports are sorted in the same manner as described for the **-nworst** option. This option cannot be used in summary or skew reports, or if the **-launch**, **-capture**, **-setup**, or **-hold** options are used. To check the quality of a balanced clock tree network, you can generate two latency reports, one with **-min** and one with **-max**.

-nworst worst_entries

Specifies the number of worst report entries to be reported per clock domain. The default value is 1. Entries are sorted with respect to the attribute of interest (transition time, latency, or skew) specified with **-type report_type**.

The worst entries are those most likely to cause a violation. For example, if you request a latency report using **-setup** and **-capture**, the smallest *worst_entries* are listed, sorted in ascending order, because small capture latencies for setup paths are more likely to lead to a violation than large capture latencies. For skew reports, the worst entries always correspond to the largest skews over the specified domain. The above definition of "worst" can be overridden by use of the **-min** or **-max** options. This option cannot be used in summary reports.

-greater_than lower_limit

Indicates that only those entries whose attribute value (latency, transition time, or skew) is greater (more positive) than *lower_limit* are shown. This option cannot be used in summary reports.

-lesser_than upper_limit

Indicates that only those entries whose attribute value (latency, transition time, or skew) is less (more negative) than *upper_limit* are shown. This option cannot be used in summary or skew reports.

-slack_lesser_than slack_upper_limit

Indicates that only those entries whose slack value is less (more negative) than *slack_upper_limit* are shown. For skew report entries, slack is the worst slack over all paths launched by the from-pin and captured by the to-pin. For transition time or latency report entries, slack is defined as the worst slack of all paths either launched by a transition at the sink pin (if **-launch** is used) or captured by a transition at the sink pin (if **-capture** is used). Using this filter can greatly increase the runtime of this report. However, when used with **-capture** the effect on runtime should be small, since the tool is able to make use of cached slack values to avoid expensive recomputation. This option cannot be used in summary reports.

-include_uncertainty_in_skew

Indicates that the user-defined uncertainty between the sequential devices in a launch/capture pair is to be considered a component of skew. This option can be used only in skew or summary reports.

-verbose

Indicates that a more detailed report is to be generated. Instead of a single line per pin, verbose reports trace the entire source-to-sink path through a clock network to show how the final reported attribute (skew, latency, or transition time) was accumulated over the course of the path. This option

cannot be used in summary reports.

-show_clocks

Indicates that the launching and capturing clocks are shown for every interclock skew entry in the report. This is useful if the *from_clock_list* or the *to_clock_list* contains more than one clock each. This option can only be used in interclock skew reports.

-nosplit

Prevents line-splitting and facilitates writing software to extract information from the report output. By default, most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-significant_digits digits

Specifies the number of digits after the decimal point to be displayed for time values in the generated report. Allowed values are 0-13. The default value is determined by the **report_default_significant_digits** variable, whose default value is 2. Use this option if you want to override the default. This option controls only the number of digits displayed, not the precision used internally for analysis. For analysis, the tool uses the full precision of the platform's fixed-precision, floating-point arithmetic capability.

-nets

Shows nets in verbose path traces. The default is not to show nets. To show the delay for the nets, use the **-input_pins** option. This option is similar to its counterpart in the **report_timing** command.

-capacitance

Indicates that total (lump) capacitance be shown in verbose path traces. The default is not to show capacitance. For each driver pin, the total capacitance driven by the driver is displayed in a column preceding both incremental path delay and transition time. When **-nets** is specified, the capacitance is printed on the lines with nets instead of the lines with driver pins. This option is similar to its counterpart in the **report_timing** command.

-attributes

Shows in verbose path traces the attributes specified in the **timing_report_attributes** variable. The current set of attributes supported are **dont_touch**, **dont_use**, **map_only**, and **size_only** for cells, and **dont_touch** and **ideal_net** for nets. This option is similar to its counterpart in the **report_timing** command.

-physical

Shows the locations of the pins and the capacitive loads for the pins and nets in verbose path traces. The loads are displayed as a pair of values of which the first is the wire capacitance of the net and the second value is the total capacitance driven by the driver. If the pin location cannot be determined, the cell location is displayed, with the coordinates in microns. This option is similar to its counterpart in the **report_timing** command.

-max

Specifies that the reports are sorted by maximum latencies or transition times. The **-min** and **-max** options are mutually exclusive. If neither option

is specified, the reports are sorted in the same manner as described for the **-nworst** option. This option cannot be used in summary or skew reports, or if the **-launch**, **-capture**, **-setup**, or **-hold** options are used. To check the quality of a balanced clock tree network, you can generate two latency reports, one with **-min** and one with **-max**.

-fall

Indicates that the active transition is a falling edge for sequential device clock pins in the current report. The **-rise** and **-fall** options are mutually exclusive. If neither option is specified, the active transition at a latch or flip-flop is deduced from the launch or capture role and the behavior of the sequential device itself. This option enables you to answer "what if" questions regarding latency and transition time at sequential device clock pins. This option cannot be used in summary or skew reports.

-capture

Indicates that only pins capturing data are to be used in the report, and that the latencies or transition times reported must correspond to those used by the **report_timing** command for sequential device clock pins that are capturing data. In skew reports, the role is implicit from the from-to sense indicated by the *from_list* and the *to_list*. In all other reports, the **-launch** and **-capture** options are mutually exclusive. If neither option is specified, **-launch** is assumed. This option cannot be used in summary or skew reports.

-hold

Indicates that only the hold data path is to be used in the report, and that the skews, latencies, or transition times reported must correspond to those used by the **report_timing** command in the verification of hold constraints. The **-setup** and **-hold** options are mutually exclusive. If neither option is specified, **-setup** is assumed. This option cannot be used in summary reports.

DESCRIPTION

This command generates a report of clock timing information for the current design.

Several reporting types allow you to examine skew, latency, and transition time attributes of a specified clock network or subnetwork at various levels of generality. By default, the report displays the values of these attributes only at sink pins (that is, the clock pins of sequential devices) of the clock network. Use the **-verbose** option to display source-to-sink path traces. If you specify several clock domains, **report_clock_timing** generates a separate subreport for each.

At the highest level of abstraction is the summary style report, which provides only a list of maxima and minima of the skew, latency, and transition time attributes over the given networks. At a lower level of abstraction are the transition, latency, and skew type reports, called list style reports, in which you can sort, filter, and display the worst set of sink pins in the given network with respect to a single attribute of interest. For skew reports, each report entry is a pair of sink pins and their relative skew. For transition time or latency reports, each entry corresponds to a single sink pin. The lowest level of abstraction is provided by verbose mode, which replaces every sink pin in a list style report by a corresponding source-to-sink path trace.

In both summary and list style reports, the right column is an attributed column.

Corresponding to each sink pin, the set of character symbols in this column indicates the following:

Symbol	Meaning
w	Worst-case operating condition
b	Best-case operating condition
r	Rising transition
f	Falling transition
p	Propagated clock to this pin
i	Clock inversion to this pin
-	Launching transition
+	Capturing transition

In verbose mode, back-annotations on path elements in the timing path are indicated using a character symbol. For definitions of these character symbols, see the man page for the **report_timing** command.

Skews reported by **report_clock_timing** are local skews only. Local skew exists from one sink pin to another only as long as their associated sequential devices are connected via a data path in the appropriate from-to sense. Note that even if all data paths between the sequential devices are false because of user-defined exceptions, the skew still qualifies as local skew if the devices are connected topologically.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows a typical summary style report:

```
prompt> report_clock_timing -type summary
*****
Report : clock timing
        -type summary
        -nworst 1
Design : xor_testcase
Version: W-2004.12-GSHELL-LCA1
Date   : Tue Nov 20 06:17:33 2004
*****  
  
Clock: CK1
-----  
Maximum setup launch latency:
    flop9/CP           3.08      rp-+
  
Minimum setup capture latency:
    or2_3/B            1.15      fpi-+
```

Minimum hold launch latency:			
or2_3/B	1.15		fpi-+
Maximum hold capture latency:			
flop9/CP	3.08		rp-+
Maximum active transition:			
or2_3/B	0.20		fpi-+
Minimum active transition:			
or2_3/B	0.09		fpi-+
Maximum setup skew:			
flop9/CP			rp-+
flop10/CP	0.87		rp-+
Maximum hold skew:			
flop9/CP			rp-+
flop10/CP	-0.21		rp-+

The following example displays the five worst setup skews in the clock network of CLK1, taking uncertainty into account:

prompt> report_clock_timing -clock CLK1 -type skew -setup \	-nworst 5 -include_uncertainty_in_skew			

Report : clock timing				
-type skew				
-nworst 5				
-setup				
-include_uncertainty_in_skew				
Design : multi_domain

-----

```

The following example displays the five worst launching latencies for hold paths in the clock network of CLK2:

```

prompt> report_clock_timing -clock CLK2 -hold -launch -nworst 5 \
-type latency

```

```

*****
Report : clock timing
    -type latency
    -launch
    -nworst 5
    -hold
Design : multi_domain
Version: W-2004.12-GSHELL-LCA1
Date   : Tue Nov 20 06:55:56 2004
*****

```

Clock: CLK2

Clock Pin	Trans	Source	Network	Total	---	Latency	---
f1_2/CP	0.04	0.00	1.00	1.00		rpi-+	
f1_3/CP	0.00	0.01	1.00	1.01		fp-+	
f2_1/CP	0.01	0.01	2.00	2.01		rp-+	
f1_1/CP	0.00	0.00	3.00	3.00		rpi-+	
f3_2/CP	0.00	0.00	3.00	3.00		fpi-+	

The following example demonstrates how to request a verbose report showing the worst local skew from f2_2/CP to any other sink pin:

```

prompt> report_clock_timing -type skew -verbose -from f2_2/CP

```

```

*****
Report : clock timing
    -type skew
    -verbose
    -nworst 1

report_clock_tree

Reports structural and timing characteristics of a compiled clock tree.

SYNTAX

```
status report_clock_tree
[-clock_trees clock_tree_list]
[-summary]
[-structure]
[-drc_violators]
[-settings]
[-exceptions [-show_all_sinks]]
[-from from_list | -to to_list]
[-operating_condition condition]
[-level_info]
[-high_fanout_net net_or_pin_list
  | -premesh
  | -postmesh]
[-nosplit]
[-all_drc_violators]
[-partial_structure_within_exceptions]
[-skew_group skew_groups_string]
```

Data Types

<i>clock_tree_list</i>	list
<i>from_list</i>	list
<i>to_list</i>	list
<i>condition</i>	string
<i>net_or_pin_list</i>	list
<i>skew_groups_string</i>	string

ARGUMENTS

-clock_trees *clock_tree_list*

Reports only the clock trees specified in *clock_tree_list*. By default, the command applies to all currently defined clock trees.

-summary

Prints a summary table for the clocks.

-structure

Prints the complete structure of the clock tree. This report will traverse through exceptions such as explicit float pins and implicit and explicit exclude pins.

-drc_violators

Lists the design rule violations that occur in the clock trees up to the endpoints (default sinks or don't touch subtrees), including violations beyond exception on stop pins, exclude pins, and float pins but excluding violations on don't buffer nets, don't touch subtrees, nets inside interface logic models, nets connected to boundary cells or pad cells.

```

-settings
    Prints the clock tree settings specified by the set_clock_tree_options
    command, and references available for buffering, design rule checking (DRC)
    constraints, the list of available routing layers, and so on.

-exceptions
    Prints a detailed list of clock tree exceptions.

-show_all_sinks
    Reports all default sinks in the exception report when used with the -exceptions option.

-from from_list
    Specifies the list of pin names whose fanout clock tree is reported.

-to to_list
    Specifies the list of pin names to which the clock paths are reported. The
    specified pins must be clock tree sink pins. This option can be used with the
    -operating_condition and -clock_trees options.

-operating_condition condition
    Reports the clock tree based on the specified condition.

-level_info
    Reports information about the clock tree by level.

-high_fanout_net net_or_pin_list
    Reports a tree built by the clock tree synthesis based high fanout net
    synthesis engine. This option can be used alone or in combination with the
    following options:

        -summary
        -structure
        -level_info
        -drc_violators
        -operating_condition
        -nosplit

-premesh
    Reports the clock network that has a clock mesh, starting from the clock root
    to the mesh driver inputs. This option treats the mesh driver inputs as stop
    pins and ignores the portion of the clock tree beneath the mesh. You can run
    this option as a stand-alone process or in combination with the following
    options:

        -clock_tree
        -summary
        -structure
        -exceptions
        -drc_violators
        -operating_condition
        -nosplit

```

-postmesh

Reports the clock network that has a clock mesh, starting from the inputs of the clock drivers that are the load pins of the clock mesh. This option does not report the clock network from the clock root to the clock mesh. You can run this option as a stand-alone process or in combination with the following options:

- clock_tree
- summary
- structure
- exceptions
- drc_violators
- operating_condition
- nosplit

When you specify this option by itself, the command reports the longest path, the shortest path, and the skew among all subtrees, starting from the load pins of the clock mesh. In addition, the clock mesh is treated as ideal so that every point of the clock mesh would have the same arrival time. Using this option with other options is equivalent to using the -from 'load pins of the clock mesh'.

-nosplit

Prevents linesplitting to allow ease of use to create scripts to extract information from the report output. By default, the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-all_drc_violators

Forces the **report_clock_tree** command to report all design rule checking (DRC) violations on the clock network, including nets and pins beyond clock exception pins.

-partial_structure_within_exceptions

Prints the part of the clock tree structure that is within explicit exclude and float pin exceptions. The clock structure beyond explicit exclude and float pin exceptions is not printed. Use the **-structure** option to print the complete clock structure.

-skew_group skew_groups_string

Report clock skew information only for the specified skew groups. You can separate each skew group with a space in the specified *skew_groups_string*. The default skew group name is **default**". For each specified skew group, the skew information will be printed for all clocks that propagate to the skew group. You can only use this option with **-clock_trees** and **-summary**. If you did not specify **-skew_group** and ran **commit_skew_group** successfully, clock skew information of all skew groups will be reported.

DESCRIPTION

The **report_clock_tree** command obtains information on clock trees. The command reports the structural and timing characteristics of a compiled clock tree.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

In the following example, the **report_clock_tree** command is run on a previously-compiled clock tree called CLK1, and the reported results are based on a clock route estimator:

```
prompt> report_clock_tree -clock_trees CLK1
```

In the following example, **report_clock_tree** is run on a precompiled clock tree named CLK1. The report includes a listing of all logical design rule checking (DRC) violations and a report of clock tree settings.

```
prompt> report_clock_tree -clock_trees CLK1 -drc_violators -settings
```

In the following example, **report_clock_tree** is run on a precompiled clock tree named CLK1. The report includes hierarchical level information about the clock tree netlist structure, the distribution clock tree delays, DRC violations, and all exceptions.

```
prompt> report_clock_tree -clock_trees CLK1 -structure -drc_violators -exceptions
```

In the following example, **report_clock_tree** is run on a precompiled clock tree named clk. The report includes a listing of all clock tree exceptions in the clock tree.

```
prompt> report_clock_tree -exceptions
```

report_clock_tree_optimization_options

Reports options used by clock tree optimization.

SYNTAX

```
status report_clock_tree_optimization_options
[-clock_trees clock_name_or_collection]
```

ARGUMENTS

-clock_trees *clock_name_or_collection*

Specifies a set of clocks to be processed. Only clock names defined through `create_clock` or `create_generated_clock` are accepted. If there is a list of clock names, the options then apply to those clocks only. By default, the options apply for all the clocks.

DESCRIPTION

This command is the UI reporting options for clock tree optimization in ICC. Before command `optimize_clock_tree` or `clock_opt`, user can use this command to report options to specific clocks if `-clock_trees` is given, or report options to all clocks that do not have the per clock option.

The options reported by this command are `enable_multicorner_optimization`, `gate_sizing`, `gate_relocation`, `preserve_levels`, `area_recovery`.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example disables `gate_sizing` to clock `PCI_CLK`. Then report the options for `PCI_CLK`.

```
prompt> set_clock_tree_optimization_options -clock_trees [get_clock PCI_CLK] \
-gate_sizing false
1
prompt> report_clock_optimization_options -clock_trees PCI_CLK
=====CLOCK: PCI_CLK=====
Enable multicorner optimization: none
Gate sizing: false
Gate relocation: true
Preserve level: false
Area recovery: true
```

1

`set_clock_tree_optimization_options(2)`
`reset_clock_tree_optimization_options(2)`

report_clock_tree_power

Calculates and reports dynamic and static power for a clock network.

SYNTAX

```
int report_clock_tree_power
[-net]
[-cell]
[-verbose]
[-include_input_nets]
[-include_register]
[-sort_mode mode]
[-nosplit]
[clock_list]
```

Data Types

<i>mode</i>	string
<i>clock_list</i>	object_list

ARGUMENTS

-net

Reports the power consumption of nets. Use the **-net** option alone, or use it with the **-cell** option to report on both nets and cells. By default, only the design's summary power information is reported when neither option is specified.

-cell

Reports the power consumption of cells. When using the **-cell** option, some entries in the power report might not apply to certain cells. The report column entry for those cells is annotated with N/A. Use the **-cell** option alone, or use it with the **-net** option to report on cells and nets. By default, only the design's summary power information is reported when neither option is specified.

-verbose

Displays additional detailed information about the power of the cells and/or nets. This option is valid only if the **-net** and/or the **-cell** options are specified.

-include_input_nets

Specifies that the power of the boundary net is included in the power report. The default is to exclude the boundary net.

-include_register

Specifies that the power of the registers is included in the power report. The default is to exclude the registers.

-sort_mode mode

Determines the sorting mode for the report order and **-nworst** selection. The valid sorting modes for the **-net** and **-cell** options are as follows:

-net option	-cell option
-----	-----
name	name
cumulative_fanout	cumulative_fanout
cumulative_fanin	cumulative_fanin
net_static_probability	cell_internal_power
net_switching_power	cell_leakage_power
net_toggle_rate	dynamic_power
total_net_load	

When using **-net** and **-cell** and specifying a sorting mode, you must select a sorting mode that is valid for both options. The mode is used for both the cell and the net reports.

If you do not explicitly set the sorting mode, a default is chosen based on the mode of the **report_clock_tree_power** command:

Mode	Implicit default
-----	-----
-net	net_switching_power
-cell	cell_internal_power
-net -cell	dynamic_power

-nosplit
Prevents line-splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

clock_list
Specifies a list of clock objects. The list can be the name of the clock used in the **create_clock** command, or a list of clock port names.
If a *clock_list* is not specified, all clock objects in the current design are considered.

DESCRIPTION

The **report_clock_tree_power** command calculates and reports power for a clock network. The probabilistic estimation algorithm functions on nets that are not explicitly annotated with switching activity values. During the probabilistic propagation, **report_clock_tree_power** uses the startpoint nets' switching activity values, if available, when computing the switching activity values for internal nets. The switching activity values are retained for any nets that were annotated with the **set_switching_activity** command. The values are not overwritten during the probabilistic propagation.

The options enable you to specify cells and/or nets for reporting. The default operation is to display the summary power values for only the current design.

The **-verbose** option displays more detailed power information.

The **-include_input_nets** and **-sort_mode** options enable filtering of objects that are selected by **report_clock_tree_power**. The **-include_input_nets** option also affects the way that the design's power values are computed by including the clock input net in the design's totals. The **-include_register** option affects the way that the design's power values are computed by including the power consumption of the registers. The **-**

sort_mode option also affects the formatting of the power reports by modifying the order of nets and/or cells that are displayed by **report_clock_tree_power**.

If they are not specifically annotated with switching activity information, all input ports and black-box cell outputs are assumed to have a toggle rate of

$$2 * sp * (1-sp) * fclk$$

where *sp* is the static probability (the default is 0.5), and *fclk* is the frequency of the object's related clock.

Power analysis uses any back-annotated net loads during the power calculation. For nets that do not have back-annotated capacitance, the net load is estimated from the appropriate wire load model. If any cluster information has been annotated on the design (Floorplan Manager), Power Compiler uses the improved capacitance estimates from the cluster's wire loads.

When invoked from within dc_shell (Design Compiler), the **report_clock_tree_power** command first checks out a Power Compiler license. If a license is not available, the command terminates with an error message. Otherwise, the command proceeds normally. At the completion of the command, the Power Compiler license is released. To keep the license at the completion of the **report_clock_tree_power** command, set the variable **power_keep_license_after_power_commands** to **true**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows a **report_clock_tree_power** summary report. It reports all clock nets in the design.

```
prompt> report_clock_tree_power
```

report_congestion

Reports the congestion statistics.

SYNTAX

```
status report_congestion
[-search_repair | -no_reroute]
[-grc_based
{-grc_number grc_number}]
[-overflow_threshold threshold]
[-by_layer]
[-coords {rectangle}
| -polygon {polygon_area}]
```

Data Types

<i>grc_number</i>	int
<i>threshold</i>	int
<i>rectangle</i>	list
<i>polygon_area</i>	list of points

ARGUMENTS

-search_repair

Specifies the routing will include the search and repair stage when performing the global routing to generate the congestion map. In other words, the routing will include the ,Äúrip-and-reroute,Äù stages. In this mode, the congestion number is better than that of the default mode, which does not include ,Äúrip-and-reroute,Äù stages.

This option and the no_reroute option are mutually exclusive.

-no_reroute

Specifies not to run global routing and reports the congestion map that is inside the design library. When you run **-report_congestion**, you should perform global routing to generate and report a new congestion map. By default, the command always runs the global routing and generates a new congestion map. When you specify this option, the global routing will not be performed and the existing congestion map will be reported instead. It is possible that the existing congesting map is not up to date, so you need to ensure that the existing congestion map is valid and up to date when using this option.

-grc_based

Specifies that the congestion reporting will be reported by each GRC (Global Routing Cell). In this mode, the worst 10 GRCs will be reported.

-grc_number grc_number}

Specifies the worst GRC number to be displayed in the -grc_based mode. When this option is set, the command goes into GRC based report mode automatically.

-overflow_threshold threshold

Specifies GRC overflow threshold to be displayed in the **-grc_based** mode, and

the command will report all the GRCs with either horizontal overflow or vertical overflow larger than the specified value. When this option is set, the command goes into GRC based report mode automatically.

-by_layer

Specifies that the congestion reporting will be reported by each routable layer.

-coords {rectangle}

Specifies a user-defined region, and this command will report the congestion statistics for that specific region. The format of a rectangle specification is {llx lly urx ury}. The coordinates of the rectangle are in microns. This option and the polygon option are mutually exclusive.

-polygon {polygon_area}

Specifies a user-defined rectilinear polygon area, and this command will report congestion statistics for that area. Define the rectilinear polygon area by specifying the coordinates of all its corners in the format of {{x1 y1} {x2 y2} {x3 y3}...}. The units of the *polygon_area* are in microns.

DESCRIPTION

This command will run global routing, generate a "fresh" congestion map, and report the congestion statistics for the current design. This command creates an on-disk file in your Milkyway database.

The report contains congestion-related parameters, congestion violations, and track usage.

By default, this command will always run global routing, generate a "fresh" congestion map, and report it. When the setting 'set_route_mode_options -zroute true' is done, Zroute global routing will be employed for congestion map generation.

EXAMPLES

The following example runs the **report_congestion** command.

```
prompt> report_congestion
prompt> report_congestion -search_repair
```

SEE ALSO

route_global(2)

report_congestion_options

Reports congestion options in the design.

SYNTAX

```
integer report_congestion_options
[-all]
id_list
```

ARGUMENTS

```
-all
    Specifies to report all congestion options.

id_list
    Reports congestion options with the specified ids.
```

DESCRIPTION

The **report_congestion_options** command reports the congestion options in the design. If **-all** is used, all congestion options in the design will be reported. If a list of ids is specified, those congestion options will be reported. The report will first report the design-wide congestion options. It will then report the regional congestion options, if any. The regional congestion options report includes the id, the coordinates, and the values.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example report of the congestion options:

```
prompt> report_congestion_options -all

Report congestion options:
*****
Congestion parameters for the design:
    Horizontal threshold: 0.8 (default)
    Vertical threshold: 0.8 (default)
    Maximum utilization: 0.95 (default)
Regional congestion options:
    ID 0: {0 0 20 20}, MAX_UTIL: 0.5
*****
```

SEE ALSO

`remove_congestion_options(2)`
`report_congestion(2)`
`set_congestion_options(2)`

report_constraint

Displays constraint-related information about a design.

SYNTAX

```
status report_constraint
[-all_violators]
[-verbose]
[-significant_digits digits]
[-max_area]
[-max_delay]
[-critical_range]
[-min_delay]
[-max_capacitance]
[-min_capacitance]
[-max_transition]
[-max_fanout]
[-cell_degradation]
[-min_porosity]
[-max_dynamic_power]
[-max_leakage_power]
[-max_net_length]
[-connection_class]
[-multiport_net]
[-nosplit]
[-max_toggle_rate]
[-max_total_power]
[-scenario scenario_list]
```

Data Types

<i>digits</i>	integer
<i>scenario_list</i>	list

ARGUMENTS

-all_violators

Displays a summary of all of the optimization and design rule constraints with violations in the current design. The **-verbose** option provides detailed information about constraint violations. Multiple violations for a given constraint are listed from the most to least violation.

-verbose

Displays more detail about constraint calculations.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are to be reported. The *digits* value must be between 0 and 13. The default value is 2. This option overrides the value set by the **report_default_significant_digits** variable.

-max_area
Displays only the max_area constraint information. The default is to display all optimization and design rule constraints.

-max_delay
Displays only the max_delay and setup information. The default is to display all optimization and design rule constraints.

-critical_range
Displays only the critical_range information. The critical_range is a design rule used to inform the optimization engine that it should optimize near critical paths along with the most critical path. The default is to display all optimization and design rule constraints.

-min_delay
Displays only the min_delay and hold information. The default is to display all optimization and design rule constraints.

-max_capacitance
Displays only the max_capacitance constraint information. The max_capacitance constraint is a design rule used to limit total capacitance on a net. The default is to display all optimization and design rule constraints.

-min_capacitance
Displays only the min_capacitance constraint information. The min_capacitance constraint is a design rule used to limit total capacitance on a net. The default is to display all optimization and design rule constraints.

-max_transition
Displays only the max_transition constraint information. The max_transition constraint is a design rule used to limit transition time on a net. The default is to display all optimization and design rule constraints. If the library uses the cmos2 delay model, this option shows the max_edge_rate information.

-max_fanout
Displays only **max_fanout** constraint information. The **max_fanout** constraint is a design rule used to limit fanout_load on a net. The default is to display all optimization and design rule constraints.

-cell_degradation
Displays only **cell_degradation** constraint information. The **cell_degradation** is a design rule used to limit total capacitance on a net. This option differs from the max_capacitance rule, in that the total capacitance that can be driven by a cell is a function of the transition times at the inputs of the cell. The default is to display all optimization and design rule constraints.

-min_porosity
Displays only the min_porosity constraint information. The min_porosity constraint is an optimization constraint for routability. The default is to display all optimization and design rule constraints.

-max_dynamic_power
 Displays only the max_dynamic_power constraint information. The default is to display power constraint information. Queries for power constraint information are only valid if a power-related license is available.

-max_leakage_power
 Displays only the **max_leakage_power** constraint information. The default is to display power constraint information. Queries for power constraint information are only valid if a power-related license is available.

-max_net_length
 Displays only max_net_lengthconstraint information. The max_net_length constraint is a design rule used to limit route length on a net. The default is to display all optimization and design rule constraints.

-connection_class
 Displays only the connection_class constraint information. The connection_class constraint is displayed only if there is a connection_class violation.

-multiport_net
 Displays only the multiport_net constraint information. The multiport_net constraint is displayed only if the attribute **fix_multiple_port_nets** is set to the default value of **none**.

-nosplit
 Prevents line-splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds its column's width, the next field begins on a new line, starting in the correct column.

-max_total_power
 Displays only the max_total_power constraint information. The default is to display power constraint information. Queries for power constraint information are only valid if a power-related license is available.

-scenario scenario_list
 Reports constraints for given list of scenarios of a multiscenario design. Inactive scenarios will be skipped in the report. Each scenario is reported separately. If this option is not given, report_constraint will report constraints on all active scenario except -all_violators and -verbose option. With these two options and without the -scenario option, report_constraints will only report constraints on current scenario.

DESCRIPTION

The **report_constraint** command displays the following information for the constraints on the current design:

- Whether the constraint was violated or met
- By how much the constraint value was violated or met

- The design object that was the worst violator.

The maximum delay information shows cost by path group. This includes violations of setup time on registers or ports with output delay as well as violations of **set_max_delay** commands. The total maximum delay cost is the sum of each group's weighted cost. For details on creating path groups, refer to the **group_path** command man page. To see the current path groups in the design, use the **report_path_group** command.

The minimum delay cost includes violation of hold time on registers or ports with output delay as well as violations of **set_min_delay** commands.

Multicorner-Multimode Support

By default, this command uses information from all active scenarios. You can select different scenarios by using the **-scenario** option.

EXAMPLES

The following example shows brief constraint information for the current design:

```
prompt> report_constraint
```

```

report_critical_area

Calculates the critical area of the design.

SYNTAX

```
status report_critical_area
[-particle_distr_func_file filename]
[-input_layers layerlist]
[-fault_type short | open]
[-tsmc_encr_particle_distr_file]
[-layer_alias_DSD_format layeraliaslist]
[-suppress_zeros_in_report]
[-multiparticle_report_format]
```

Data Types

<i>filename</i>	string
<i>layerlist</i>	list
<i>layeraliaslist</i>	list

ARGUMENTS

```
-particle_distr_func_file filename
    Specifies the particle probability function file. It can be in ASCII or
    Synopsys encrypted format.
    If you do not specify this option, the tool uses an internal default particle
    probability function.

-input_layers layerlist
    Specifies the metal layers (in the format m1 m2 m3 ... or M1 M2 M3 ... or
    metal1 metal2 metal3 ...) for which critical area should be calculated. The
    metal layer can also be specified as in the technology file.
    If you do not specify this option, the tool calculates critical area for all
    metal layers.

-fault_type short | open
    Specifies the fault type.
    If you do not specify this option, the tool calculates the short critical area.

-tsmc_encr_particle_distr_file
    Specifies that the particle distribution function is in TSMC encrypted
    format.
    If you do not specify this option, the tool assumes the default format for
    the particle probability function.

-layer_alias_DSD_format layeraliaslist
    Specifies the layer alias used for defect size distribution (DSD) of each
    layer. These numbers indicate the number of layers for each of these metal
    types. Each type of metal layer will have a DSD curve and D0 specified in the
    particle-distribution file. The order of these aliases is from bottom to top.
    M1 is always a separate type. Then above it are Mx layers, My layers, Mz or
    Mt layers, and Mr layers. Use this option along with the -
```

multilayer_DSD_format option.

-suppress_zeros_in_report
If critical area for a window is zero, this option suppresses that entry from the output heatmap file. This helps to reduce the size of the heatmap file. The default is to report windows with zero critical area.

-multiparticle_report_format
Specifies that the tool calculates and reports the critical area of each particle separately in the heatmap file. If you specify this option, windows with zero critical area are automatically suppressed to reduce the size of the heatmap file.
The default is to calculate the average critical area for all particles and report a single value.

DESCRIPTION

This command is used to calculate the critical area of a design. It can be used to calculate short critical area or open critical area. This command calculates the average critical area per metal layer. The input can be specified in two formats: a particle probability file or a multilayer defect size distribution (DSD) format. A particle probability file can be specified in text format or in Synopsys encrypted format. Use the **process_particle_probability_file** command to encrypt the particle probability file. The input in multilayer DSD format can be a text file or a TSMC encrypted file. If you do not specify an input particle probability file, a default particle probability function is used. The output is a text format heatmap file that is written to the current working directory. This heatmap is also stored as an attachment and can be displayed. A separate display heatmap is created for each fault type and each metal layer.

The layer aliases are specified in x, y, z, t, r format strictly in this order. This option is used only for input files in TSMC format. You must provide an integer value for each of x, y, z, t, r. The definitions for each of them should be in the TSMC format input file. 'x' layers starting from M2 going up use the 'Mx' particle distribution definition from input file. The next 'y' layers use the 'My' definition and so on. A nonzero value of 'z' is provided for 90 nm technology. A nonzero value of 't' is specified for 65 nm technology. A nonzero value for 'z' and 't' at the same time is treated as an error. The last 'r' layers use the 'Mr' particle distribution definition from input file.

For best results, run this command on the design with zero or minimum DRCs.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example calculates open critical area on metal layers m2 and m3 using the default particle probability function:

```
prompt> report_critical_area -fault_type {open} \
 -input_layers {m2 m3}
```

SEE ALSO

`process_particle_probability_file(2)`

report_crpr

Reports the clock reconvergence pessimism calculated between specified register clock pins or ports.

SYNTAX

```
status report_crpr
    -from from_latch_clock_pin
    -to to_latch_clock_pin
    [-from_clock from_clock]
    [-to_clock to_clock]
    [-setup | -hold]
    [-significant_digits digits]
```

Data Types

<i>from_latch_clock_pin</i>	string
<i>to_latch_clock_pin</i>	string
<i>from_clock</i>	string
<i>to_clock</i>	string
<i>digits</i>	integer

ARGUMENTS

```
-from from_latch_clock_pin
    Specifies the clock pin of the launching sequential device or clock gating
    check to be reported. A constrained input port may also be used.

-to to_latch_clock_pin
    Specifies the clock pin of the capturing sequential device or clock gating
    check to be reported. A constrained output port may also be used.

-from_clock from_clock
    Specifies the clock that fans out to the launching sequential device.

-to_clock to_clock
    Specifies the clock that fans out to the capturing sequential device.

-setup
    Reports the clock reconvergence pessimism for a setup data path. The -setup
    and -hold options are mutually exclusive. If neither option is specified, -setup
    is assumed.

-hold
    Reports the clock reconvergence pessimism for a hold data path. The -setup
    and -hold options are mutually exclusive. If neither option is specified, -setup
    is assumed.

-significant_digits digits
    Specifies the number of digits to the right of the decimal point that are to
    be reported. Allowed values are 0-13. If this option is not specified, the
    number of significant digits is determined by the
```

report_default_significant_digits variable, which has a default value of 2.

DESCRIPTION

This command reports the clock reconvergence pessimism calculated between specified register clock pins or ports. The command displays the following information about the calculation of the clock reconvergence pessimism between the two specified sequential elements:

- The name of the common pin in the clock network.
- The clock edges (rising or falling) that propagate through the common point to the launching and capturing registers.
- The value of the variable **timing_crpr_threshold_ps**.
- A tabulation of the arrival times for both clock edges at the common point and their associated clock reconvergence pessimism (crp_rise and crp_fall).
- The clock reconvergence pessimism used along with the reasoning behind the selection of crp_rise or crp_fall used for that report.
- The potential range of accuracy of the clock reconvergence pessimism value that will appear in the corresponding timing report. The range of accuracy depends upon the value of the **timing_crpr_threshold_ps** variable.

If the **timing_remove_clock_reconvergence_pessimism** variable is set to false, clock reconvergence pessimism removal is inactive and no report can be generated. To determine the current value of the variable, type the following command:

```
prompt> printvar timing_remove_clock_reconvergence_pessimism
```

The **-from_clock** and **-to_clock** options allow you to generate a report for only the specified clocks. By default, a report is issued for all clocks that fanout to each sequential device.

Two clock reconvergence pessimism values are calculated for each potential common point in the design:

- The crp_rise value is calculated from rising arrival times at the common point.
- The crp_fall value is calculated from falling arrival times at the common point.

The value of clock reconvergence pessimism used in the report depends upon what clock edges propagate through the common point to the clock pins of the launching and capturing devices. For example, if a rising edge through the common point triggers the launching device and also triggers the capturing device, then a rising clock reconvergence pessimism value (crp_rise) is used. Similar reasoning applies for a falling edge propagating through the common point and subsequently launching and capturing data leading to a falling clock reconvergence pessimism value being used (crp_fall). If a rising edge through the common point launches the data and a falling edge through the common point captures it, then a mismatch in sense occurs.

If a mismatch occurs and the **timing_clock_reconvergence_pessimism** variable is set to **normal**, then the minimum of crp_rise and crp_fall is used. If a mismatch occurs and the variable is set to **same_transition**, then the clock reconvergence pessimism is reported as 0. This selection process is reported in the selection details section of the report. To determine the current value of the **timing_clock_reconvergence_pessimism** variable, type the following command:

```
prompt> printvar timing_clock_reconvergence_pessimism
```

When the capturing sequential device is a level-sensitive latch 2 clock reconvergence pessimism values are reported. The first value corresponds to the opening edge of the latch and appears in the timing report. The second value corresponds to the closing edge of the device. The selection details section also reports the decision making process behind both clock reconvergence pessimism values. In this case, since the opening and closing clock edges at the latch will always be different, there will always be a mismatch in clock edges for one of them.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example reports the clock reconvergence pessimism calculated between the *ffa* and *ffd* sequential elements for a setup data path:

```
prompt> report_crpr -from ffa/CP -to ffd/CP -setup

```

1

The following example displays a report where the launching device is a flip-flop and the capturing device is a latch. In this case, the mismatch in clock edges occurs for the clock reconvergence pessimism corresponding to the closing edge at the latch.

prompt> report_crpr -from reg1/CP -to lat2/G

```

*****
Report : CRP Calculation
Design : borrow
Version: 2004.12
Date   : Mon Nov 1 15:44:20 2004
*****
```

Startpoint: reg1 (rising edge-triggered flip-flop clocked by clk)
 Endpoint: lat2 (positive level-sensitive latch clocked by clk)

Common Point: clk_buf/Z
 Common Clock: clk
 Launching edge at common point: RISING
 Latch open edge at common point: RISING
 CRPR threshold: 0.01

Arrival Times	Early	Late	CRP
Rise	2.1229	2.6529	0.5300
Fall	2.0868	2.7868	0.7000

Selection Details

```

-----
Edge Match (opening): Match, using rise CRP
Edge Match (closing): Mismatch, using min(rise CRP, fall CRP)
-----
```

clock reconvergence pessimism (open edge)	0.5300
clock reconvergence pessimism (close edge)	0.5300

Range of accuracy of CRP in report_timing, due to value
 of timing_crpr_threshold_ps: 0.5200 <= CRP <= 0.5300

1

SEE ALSO

`timing_crpr_threshold_ps(3)`
`timing_remove_clock_reconvergence_pessimism(3)`

report_cts_batch_mode

Reports the clock tree synthesis batch mode status.

SYNTAX

```
status report_cts_batch_mode
```

ARGUMENTS

None

DESCRIPTION

To reduce runtime in script that call CTS commands many times, in some cases, one clock at a time, the set command turns on the batch mode. It skips CTS pre and post process whenever it can. For example, if 3 compile_clock_tree commands are called, the first call will run the CTS pre-process, but skipped the post process. The second and the third calls will skip both pre and post process. The following command, like reset_cts_batch_mode, save_mw_cel or other trigger commands will make up the CTS post process.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
set_cts_batch_mode  
compile_clock_tree -clock_trees clk1  
compile_clock_tree -clock_trees clk2  
  
report_cts_batch_mode  
optimize_clock_tree  
balance_inter_clcok_delay  
reset_cts_batch_mode
```

SEE ALSO

```
reset_cts_batch_mode(2)  
set_cts_batch_mode(2)
```

report_delay_calculation

Displays the actual calculation of a timing arc delay value for a cell or net.

SYNTAX

```
status report_delay_calculation
-min
-max
-from from_pin
-to to_pin
[-nosplit]
[-crosstalk]
[-from_rise_transition from_rise_value]
[-from_fall_transition from_fall_value]
```

Data Types

<i>from_pin</i>	string
<i>to_pin</i>	string
<i>from_rise_value</i>	float
<i>from_fall_value</i>	float

ARGUMENTS

-min

Specifies that the report must show how a minimum delay value is computed. If you do not specify this option, the report shows how a maximum delay value is computed.

-max

Specifies that the report must show how a maximum delay value is computed. This is the default behavior. This option cannot be used with the **-min** option.

-from *from_pin*

Specifies the starting point of a timing arc within a design. This option must be used along with **-to *to_pin***. When this option is specified, you cannot specify a collection of multiple pins. For a cell timing arc, the pins must represent a common leaf cell's input and output pins, which have a timing arc specified between them in the library. For a net timing arc, the pins must be a driver and a load on a common net. The specified pins must be associated with library cell instances connected by the net. Port names are allowed in place of a pin name for net arcs. A hierarchical pin is not a valid pin for this option.

-to *to_pin*

Specifies the ending point of a timing arc within a design. This option must be used along with **-from *from_pin***. When this option is specified, you cannot specify a collection of multiple pins. For a cell timing arc, the pins must represent a common leaf cell's input and output pins, which have a timing arc specified between them in the library. For a net timing arc, the pins must be a driver and a load on a common net. The specified pins must be associated with library cell instances connected by the net. Port names are allowed in

place of a pin name for net arcs. A hierarchical pin is not a valid pin for this option.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the delay data is listed in fixed-width columns. If the text for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-crosstalk

Reports the crosstalk information for a net arc. The arc is specified by *from_pin* and *to_pin*.

-from_rise_transition *from_rise_value*

Specifies the from rise transition value used by the delay calculation. The specified value is in main library units.

-from_fall_transition *from_fall_value*

Specifies the from fall transition value used by the delay calculation. The specified value is in main library units.

DESCRIPTION

This command provides detailed timing calculation information about the specified cell or net timing arc. You can use this information for debugging or verifying timing data in a technology library. Before using this command to display details of a cell timing arc, read the technology library file into the system using the **read_lib** command. The **read_lib** command automatically compiles the library and enables the **report_delay_calculation** command for cell timing arcs. Otherwise, the built-in security mechanism terminates the command when issued for a cell timing arc. This restriction does not apply to net timing arcs.

Both operating conditions and wire load models are taken into account when making delay calculations. Timing ranges are not taken into account because they typically apply to an entire path.

The **-crosstalk** option on net arc reports the aggressor and victim information for both rise and fall. The option prints coupling capacitance, the driving library cell, and the clocks reaching the net (both victim and aggressor). The aggressors have "Switching Bump," which is used for prioritizing the aggressors and also have aggressor attributes (active or screened).

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following examples show reports generated using **report_delay_calculation**:

```

report_delay_estimation_options

Reports the parameters that influence delay estimation.

SYNTAX

```
status report_delay_estimation_options
```

ARGUMENTS

The **report_delay_estimation_options** command has no arguments.

DESCRIPTION

The **report_delay_estimation_options** command reports the parameters that influence the delay calculation the tool uses in placement and routing estimation.

The scaling factors are scenario aware. When you switch the current scenario, only the scaling factors for the current scenario will be printed out.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example runs the **report_delay_estimation_options** command:

```
prompt>set_delay_estimation_options
-min_unit_horizontal_capacitance 0.0015 -min_unit_vertical_capacitance 0.0010 \
-min_unit_horizontal_resistance 0.15 -min_unit_vertical_resistance 0.10 \
-max_unit_horizontal_capacitance 0.0030 -max_unit_vertical_capacitance 0.0035 \
-max_unit_horizontal_resistance 0.25 -max_unit_vertical_resistance 0.20 \
-min_unit_horizontal_capacitance_scaling_factor 1.0015 \
-min_unit_vertical_capacitance_scaling_factor 1.0010 \
-min_unit_horizontal_resistance_scaling_factor 1.15 \
-min_unit_vertical_resistance_scaling_factor 1.10 \
-max_unit_horizontal_capacitance_scaling_factor 1.0030 \
-max_unit_vertical_capacitance_scaling_factor 1.0035 \
-max_unit_horizontal_resistance_scaling_factor 1.25 \
-max_unit_vertical_resistance_scaling_factor 1.20 \
-max_via_resistance 0.25 -max_via_resistance 0.20 \
-max_via_resistance_scaling_factor 1.25 -max_via_resistance_scaling_factor 1.20

report_design

Displays attributes of the current design.

SYNTAX

```
int report_design
[-nosplit]
[-physical]
```

ARGUMENTS

-nosplit
Prevents line-splitting and facilitates writing software to extract information from the report output. Design information is listed in fixed-width columns. If information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-physical
Reports details about the physical state of the design in various sections.
Design Statistics Section: number of macro cells, module cells, pins, IO pad cells, IO pins, nets and average pins per net.
Chip Utilization section: Total Area for: macro cells, std cells, blockages, pad cells, core area, pad core area, chip area. As well, reports width and height for chip and pad core. Also core width/height if core is not rectilinear.
Utilization: std cell [(std cell area) / (core - blockage area)] cell/core
[(std cell + macro area)/(core area)] cell/chip [(std cell + macro + pad area) / (chip area)]
Other: number of cell rows
Master Instantiation Section: Name of master cells, their type and instantiation count
Timing/Optimization section: Various cell type/slack statistics (if applicable)
Global Routing Information: Details about the routing (if applicable) including Bounding Box, metal layers, track details, etc
Track Assignment Information: wire length estimates/statistics
Other sections: DRC information, Ring Wiring Statistics, Stripe Wiring Statistics, User Wiring Statistics, PG follow-pin Wiring Statistics, Signal Wiring Statistics

DESCRIPTION

The **report_design** command lists information about the attributes of the design.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following is an example of a design report:

```
prompt> report_design
```

```

report_design_lib

Lists the design units contained in the specified libraries.

SYNTAX

```
int report_design_lib
[-libraries] [-designs] [-architectures] [-packages] [library_list]
```

Data Types

library_list list

ARGUMENTS

```
-libraries
    Indicates that libraries, and not their contents, are to be listed.

-designs
    Indicates that designs in libraries (Verilog modules, VHDL entities, or
    configurations) are to be listed.

-architectures
    Indicates that designs in libraries, plus their architectures, are to be
    listed.

-packages
    Indicates that packages in specified libraries are to be listed.

library_list
    Specifies a list of libraries whose contents are to be displayed. If no
    library_list is specified, all libraries are displayed.
```

DESCRIPTION

Lists the contents of specified libraries.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **report_design_lib** to list the contents of the current design libraries:

```
prompt> report_design_lib
*****

`read_file(2)`

report_design_physical

Displays design-related information for the current design.

SYNTAX

```
status report_design_physical
[-design_setup]
[-netlist]
[-floorplan]
[-route]
[-utilization]
[-all]
[-verbose]
```

ARGUMENTS

-design_setup
Reports design setup information, such as the link library, target library, search path, units (logic library, Milkyway, and technology file).
By default, the design setup information is not reported. If no option is specified, the design setup information will be reported.

-netlist
Reports the logical netlist information, such as information about the cells, nets, pins, and ports.
For cells, the reported information includes the instance type, such as macro, ILM, or physical-only cell; the gate count; and the cell area in both square microns and sites.
By default, the logical netlist information is not reported.

-floorplan
Reports floorplan information, such as information about site rows, layers, voltage areas, groups, bounds, and power domains.
By default, the floorplan information is not reported. If no option is specified, the floorplan information will be reported.

-route
Reports routing-related information, such as information about wires and via counts.
By default, the routing-related information is not reported.

-utilization
Reports various site and area utilization numbers and power net options. The utilization number reported by this command is approximately equal to that of report_placement_utilization. By default, the utilization information is not reported.

-all
Reports the design setup, logical netlist, floorplan, routing, and utilization information. The behavior is the same as if you specified the **-design_setup**, **-netlist**, **-floorplan**, **-routing**, and **-utilization** options.
By default, this information is not reported.

-verbose
 Reports additional information when you specify the **-netlist**, **-floorplan**, and **-utilization** options.
 If you specify this option with the **-netlist** option, the tool reports reference instantiation information. If you specify this option with the **-floorplan** or **-utilization** option, the tool reports the number of islands in blockage section.

DESCRIPTION

The **report_design_physical** command reports information about the current design. If you do not specify any options, the report includes design setup information and floorplan information which is reported by **-floorplan** and **-design_setup** options. The utilization number reported by this command with **-utilization** is approximately equal to that of **report_placement_utilization**.

EXAMPLES

The following is an example of a design report with the **-design_setup** and **-floorplan** options:

report_direct_power_rail_tie

Reports all the library pins on which the **direct_power_rail_tie** attribute is set to true.

SYNTAX

```
int report_direct_power_rail_tie
```

ARGUMENTS

The **report_direct_power_rail_tie** command has no arguments.

DESCRIPTION

Reports all the library pins on which the attribute **direct_power_rail_tie** is set to true.

If the value of **direct_power_rail_tie** attribute on a library pin is true, then all the pins in the design, for which this is the library pin, it won't connect it to a tieoff cell for connecting it to constant signal. Instead, it will keep them connecting to generic constant signals, so that during power routing these pins can be connected directly to power rails.

To remove **direct_power_rail_tie** attribute, use **remove_attribute**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command reports all the library pins which have the **direct_power_rail_tie** attribute set to true on them.

```
prompt> report_direct_power_rail_tie target_lib/leaf_cell/GND target_lib/  
leaf_cell/GND
```

SEE ALSO

`set_direct_power_rail_tie(2)`

report_disable_timing

Reports disabled timing arcs in the current design.

SYNTAX

```
string report_disable_timing
[-nosplit]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. By default, most design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line starting in the correct column.

DESCRIPTION

The **report_disable_timing** command reports disabled timing arcs in the current design. Timing arcs can be disabled in three ways. The first way is by using the **set_disable_timing** command. The second and third ways are both through automatically disabled arcs by the synthesis timing engine. This automatic disabling occurs in order to break timing loops or when propagating constants in the design.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example disables the timing arc of a cell named *U1/U2* from pin A to pin Z:

```
prompt> set_disable_timing {U1/U2} -from A -to Z
prompt> report_disable_timing
*****
Report : disable_timing
Design : middle
*****
Flags :      c  case-analysis
            C  Conditional arc
            l  loop breaking
            u  user-defined
            L  stored loop breaking
```

Cell or Port	From	To	Flag
U1/U2	A	Z	u
U1/U2	B	Z	L

The following example disabled the timing arc of a cell named *ff1* from pin *CP* to pin *TE* and *TI* as a result of a case-analysis constant propagation to pin *TE* of cell *ff1*. Note that the L flag appears only when such arcs exist.

```
prompt> set_case_analysis 0 {ff1/TE}
```

```
prompt> report_disable_timing
```

```
*****
Report : disable_timing
Design : middle
*****
```

```
Flags :
  c  case-analysis
  C  Conditional arc
  l  loop breaking
  u  user-defined
```

Cell or Port	From	To	Flag
ff4	CP	TI	c
ff4	CP	TE	c

SEE ALSO

```
set_case_analysis(2)
set_disable_timing(2)
```

report_distributed_hosts

Creates a detailed report on user defined distributed hosts in the farm's pool

SYNTAX

Boolean **report_distributed_hosts**

DESCRIPTION

The **report_distributed_hosts** generates a report on user defined distributed hosts in the farm's pool. The following information is displayed for each distributed processor. Farm indicates the type of the farm from which the distributed processor was acquired, one of 'lsf', 'grd', 'generic' or 'now'. Status indicates whether the distributed processor was launched by issuing 'successfully launched' on success and 'Not yet launched' when the distributed processor failed to launch or has not yet been lauched. Host Name indicates the name of the machine, grid name or lsf name from which the distributed processor was acquired. Command is the command used to launch the distributed processor.

EXAMPLES

In the following example a distributed processor is allocated from a workstation called platinum1. The processor is lauched using the **create_distributed_farm** command. The **report_distributed_hosts** command then generates a report on the processor.

```
prompt> add_distributed_hosts -farm now -32bit platinum1 1 prompt>
create_distributed_farm 1] Launched: rsh -n -l user platinum1 pt_shell -
multi_scenario -32bit -__zdpp_slave ptsrv2 16874 16859 1 /user/work PrimeTime 4106
4108 53205 Status: Forking successful Stdout: your job Stderr: **<<EMPTY>>**  

-----  
---- Waiting for 1 (of 1) distributed hosts -----  
----- prompt> report_distributed_hosts 1]  
Farm : now Status : Successfully launched Host Name: platinum1 Command : pt_shell -
multi_scenario -32bit
```

SEE ALSO

[add_distributed_hosts\(2\)](#)

report_distributed_route

Return status of a specified job and total number of available CPUs.

SYNTAX

```
integer report_distributed_route
-job jobId
```

Data Types

jobId integer

ARGUMENTS

```
-job jobId
      Enter a job ID.
```

DESCRIPTION

Return status of a specified job ID and the total number of CPUs available to use on running the job. If the job is existing and still running, then the current status will be returned. The failure will be returned if the specified job was killed or interrupted (or not existing), and no number of CPUs will be returned, either.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example is to report status of job with ID number 100 and current available CPUs.

```
prompt> report_distributed_route -job 100
```

SEE ALSO

```
set_distributed_route(2)
remove_distributed_route(2)
close_distributed_route(2)
```

report_drc_error_type

Output a formatted report on the given error types.

SYNTAX

```
status report_drc_error_type
[-type error_type | -class type_class]
[-error_view mw_error_view]
```

Data Types

<i>error_type</i>	list
<i>type_class</i>	list
<i>mw_error_view</i>	list or collection

ARGUMENTS

-type *error_type*

A list of error type ids or names on which to report. This option is mutually exclusive with the **-class** option. If both **-type** and **-class** options are omitted, reports on all types in the error view.

-class *type_class*

One or more of the type classes {Default, Open, OpenLocator, Short, Spacing}. Type class name keywords are case insensitive. If given, the report will be generated for classes in the given classes. This option is mutually exclusive with the **-type** option. If both **-type** and **-class** options are omitted, reports on all types in the error view.

-error_view *mw_error_view*

The error view on which to report on the error types. If omitted, reports on the error types in the current toplevel design cell. Specifying more than one error view causes an error.

DESCRIPTION

This command outputs a formatted report on the given error types.

EXAMPLES

The following example opens an error view named "mydesign_idrc.err" and outputs a report on an error type named "Overlap":

```
prompt> set cellId [open_mw_cel -not_as_current mydesign_idrc.err]
{mydesign_idrc}
prompt> report_drc_error_type -name Overlap -error_view $cellId
```

```
*****
```

Report	:	DRC_Error Types

```
Error view cel : mydesign_idrc
Version       : C-2009.06
Date         : Thu Dec 18 10:27:02 2008
*****
Data          Value
-----
Error type ID      1024
Error type name    Overlap
Number of errors   2
Type class         Default
Description        Metal and blockage overlap
Default error status Error Must-Fix
Bbox coordinates   {{10.000 10.000} {120.000 30.000}}
```

SEE ALSO

`create_drc_error_type(2)`
`list_drc_error_types(2)`

report_droute_options

Reports the persistent detail route options, their current value, default value, range, type, and a brief description.

SYNTAX

```
status report_droute_options
[-name ]
```

ARGUMENTS

-name name

Specifies the name or name pattern of the option to be reported. Name pattern will report all options that match it. By default, if "-name" is not specified, all droute options are reported.

DESCRIPTION

The **report_droute_options** command shows options that tune detailed router operation. These settings are persistent in the Milkyway design. Cell-persistent options are saved in cell data base by **set_droute_options** command. Before printing options, **report_droute_options** loads all droute options from currently opened cell. All options are optional. This command prints all available detailed router options, their current value, default value, range, type and a brief description. However, if you want to see a specific option or options that match a specified name pattern, use argument "-name". You can set detailed router options with command **set_droute_options**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> report_droute_options -name shiftVarWidthWire

(Integer Option for "droute" "shiftVarWidthWire" 1)
;;      range [0,2], default=0, stored in cell;
;;      0: put wide wires on routing tracks;
;;      1: shift wide wires by half-pitch if necessary to improve routing
;;      2: shift NDR wires to optimize for minSpace, maxSpace and metal_fill
;;          (experimental feature).
```

Name pattern will report all options that match it, for example M9MinEdgeLength matches 3 options:

```
prompt> report_droute_options -name M9MinEdgeLength

(Real Option for "droute" "M9MinEdgeLength4" 0.000)
;;      range [0.000,1.000], default=0.000, stored in cell;
```

```

;;      N: minEdgeLength4

(Real Option for "drouute" "M9MinEdgeLength5" 0.000)
;;          range [0.000,1.000], default=0.000, stored in cell;
;;      N: minEdgeLength5

(Real Option for "drouute" "M9MinEdgeLength6" 0.000)
;;          range [0.000,1.000], default=0.000, stored in cell;
;;      N: minEdgeLength6

prompt> report_drouute_options

Integer Option for drouute removeObsoleteStub 0
#          range [0,1], default=0, stored in cell;
;;          0: leave obsolete stubs in routing solution
;;          1: try to remove obsolete stubs at the end of each Sbox routing.

Integer Option for drouute accessPolyPin 1
#          range [0,1], default=1, stored in cell;
;;          0: ignore Poly pins,
;;          1: access Poly pins if there are any.

etc.

Real Option for drouute defaultDiodeProtect 0.000
#          range [0.000,1000000.000], default=0.000, stored in cell;
;;          N: default diodeProtection value for all unspecified output ports
;;          except top-cell ports (used when doAntennaConx == 4)
Real Option for drouute defaultGateSize 0.000
#          range [0.000,1000000.000], default=0.000, stored in cell;
;;          N: default gateSize value for all unspecified input ports

etc.

```

SEE ALSO

`set_drouute_options(2)`

report_error_coordinates

Displays the coordinates of all error objects in the error cell.

SYNTAX

```
status report_error_coordinates  
error_cell_name
```

Data Types

```
error_cell_name      string
```

ARGUMENTS

```
error_cell_name  
      Specifies the error cell of interest. The error objects in this error cell  
      will be reported.
```

DESCRIPTION

This command will list all the error objects in the given error cell. To run this command, the library containing the error cell must be opened first. Error cells can be created by commands such as DRC and LVS verification commands. The information that is reported includes:

- The type of summary being reported - The distance unit used in the library - Each error type along with a summary, the number of error objects, and the coordinates of all the error objects.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows what the output of report_error_coordinates looks like.

```
prompt> report_error_coordinates my_error_cell  
*****  
Report      : Error Coordinates  
Error cell  : stub.err

report_extraction_options

Reports the options that influence postroute extraction.

SYNTAX

```
status report_extraction_options
[-scenario scenario_list]
```

ARGUMENTS

```
-scenario scenario_list
    Reports extraction options given list of scenarios of a multiscenario design.
    Inactive scenarios will be skipped in the report. Each scenario is reported
    separately. If this option is not given, only the current scenario is
    reported.
```

DESCRIPTION

The **report_extraction_options** command reports the parameters that influence the post-route extraction.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example runs the **report_extraction_options** command.

```
prompt>set_extraction_options -max_cap_scale 1.1 -min_cap_scale 0.9 \
-max_res_scale 1.2 -min_res_scale 0.8 \
-max_ccap_scale 1.3 -min_ccap_scale 0.7 \
-max_ccap_thres 0.01 -min_ccap_thres 0.005 \
-max_ccap_ratio 0.1 -min_ccap_ratio 0.05 \
-max_process_scale 1.4 -min_process_scale 0.6 \
-no_obstruction \
-max_segment_length 100 \
-fan_out_thres 100
```

```

report_fast_mode

Reports the fast mode settings.

SYNTAX

`report_fast_mode`

ARGUMENTS

None

DESCRIPTION

Report current setting of the fast mode by the `set_fast_mode` command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> report_fast_mode
fast mode : On
no_congestion : false
```

SEE ALSO

`set_fast_mode(2)`

report_feasibility_options

Reports options set for feasibility using `set_feasibility_options` command.

SYNTAX

```
int report_feasibility_options
[-scenarios {scenario_name1, scenario_name2, ...}]
```

DESCRIPTION

The `report_feasibility_options` command reports all the options set for feasibility optimization and reportion using the command `set_feasibility_options`. Use these options to constraint feasibility place_opt and reporting commands.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows a report:

```
prompt>set_feasibility_options -group_io false -zero_path_margin 50 -
zero_wire_load_margin 100
prompt>set_feasibility_options -design_slack_threshold -3
prompt>set_feasibility_options -slack_threshold_path_group "Clk1 Clk2" -

report_filler_placement

Reports on the standard cell fillers contained in a design.

SYNTAX

```
int report_filler_placement  
[-abut]  
-lib_cell libcells
```

ARGUMENTS

-abut

Reports only the adjacent filler cells that form a consecutive pair in a cell row.

DESCRIPTION

The **report_filler_placement** command reports the types of fillers used in the design and their respective locations, based on specified list of filler cells.

If the **-abut** option is specified, the **report_filler_placement** command reports only the occurrence of two consecutive filler cells in the same cell row and their locations.

EXAMPLES

The following example reports the consecutive filler cells with the given reference library names:

```
prompt> report_filler_placement -lib_cells {0K0NA02M1 0K0BF00M3 0K0SPACER}  
                 -abut
```

The following are examples with and without the **-abut** option:

```
prompt> report_filler_placement -lib_cell FILL1BWP  
Information: xofiller!FILL1BWP!1 standard-  
cell filler is located at (311.920000, 285.040000). (APL-054)  
Information: xofiller!FILL1BWP!2 standard-

`remove_stdcell_filler(2)`

report_flip_chip_driver_bump

Issues a report of flip chip drivers and bumps matching results set with assign_flip_chip_nets command.

SYNTAX

```
status_value report_flip_chip_driver_bump
```

ARGUMENTS

None.

DESCRIPTION

This command issues a report of the driver-bump matching results. The report is in table format. Each line represents a flip chip net connection. The first column specifies the bump cell; the second column specifies the net that connects the bump and the driver; and the third column specifies the driver cell. The driver-bump connections can be set with assign_flip_chip_nets command. The following is an example of the report:

```
***** Bump / Driver Matching Net *****/
"BUMP_X_503" "REG_DATA_4[21]" "U__4_PAD_92"
"BUMP_X_502" "REG_DATA_1[10]" "U__1_PAD_81"
"BUMP_X_501" "REG_DATA_4[6]" "U__4_PAD_77"
"BUMP_X_500" "COL_ON_2" "U__2_PAD_15"
"BUMP_X_499" "REG_ADDR_4[9]" "U__4_PAD_68"
"BUMP_X_498" "REG_DATA_4[4]" "U__4_PAD_75"
"BUMP_X_497" "REG_ADDR_4[0]" "U__4_PAD_59"
"BUMP_X_496" "REG_DATA_2[29]" "U__2_PAD_100"
"BUMP_X_495" "W_FBI_ON_4" "U__4_PAD_12"
"BUMP_X_494" "REG_DATA_4[8]" "U__4_PAD_79"
"BUMP_X_493" "RE_RDY_4" "U__4_PAD_58"
"BUMP_X_492" "RE_BUSY_4" "U__4_PAD_8"
"BUMP_X_491" "REG_DATA_4[1]" "U__4_PAD_72"
"BUMP_X_490" "REG_DATA_4[16]" "U__4_PAD_87"
"BUMP_X_489" "REG_DATA_4[10]" "U__4_PAD_81"
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the results of driver-bump matching and dumps the report to a file named fc_match using redirect operator >.

```
prompt> report_flip_chip_driver_bump > fc_match
```

SEE ALSO

`assign_flip_chip_nets(2)`

report_flip_chip_type

Report the personality type of specified nets, flip chip bumps or drivers

SYNTAX

```
status_value report_flip_chip_type  
net_or_cell_list
```

Data Types

net_or_cell_list collection

ARGUMENTS

net_or_cell_list
Specifies a collection of nets or cells whose personality type will be reported. The collection must contain nets, flip chip drivers or flip chip bumps.

DESCRIPTION

This command reports personality types of specified nets, bumps or drivers.

In a flip chip design, a bump is a piece of metal at the topmost layer of the chip that forms an electrical contact to the chip's packaging. A flip chip driver is an I/O circuitry that drives or receives signals from or to the chip thru the bump. A bump and its associated driver may be placed at different locations but need to be electrically connected.

A personality type is a string associated to a net or a flip chip driver or a flip chip bump. Only drivers and bumps of identical personality type can be electrically connected to form a complete I/O circuit. Drivers and bumps without a personality type setting will have a default personality type, which is an empty string. The personality type setting stored in the design and is Milkyway persistent. This command will list the personality type for each cell.

The following is an example of the report: /*****Flip Chip Bump/Driver/Net Personality Type Report*****/

```
"BUMP_X_66" "red" "BUMP_X_252" "green" "BUMP_X_144" "red" "BUMP_X_352" "red"  
"BUMP_X_287" "BUMP_X_87" "red" "BUMP_X_57" "red" ...
```

The first column is the bump cell name, the second column is its personality type, empty is personality type not specified.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the personality type of all cells whose name start with "BUMP".

```
prompt> report_flip_chip_type [get_cells "BUMP*" -all]
```

SEE ALSO

[report_flip_chip_type\(2\)](#)

report_floorplan_data

Reports the floorplan data on one or more modules.

SYNTAX

```
status report_floorplan_data
-module module_objects
[-view view_name]
[-quiet]
```

Data Types

<i>module_objects</i>	list
<i>view_name</i>	string

ARGUMENTS

```
-module module_objects
    Specifies a list of module objects on which to report the floorplan data
    value.
    Each element in the list must be a collection, in which valid objects are
    current Milkyway design, hierarchical cells, soft macros, hard macros and
    plan groups.

-view view_name
    Specifies the view in which floorplan data will be reported.
    Valid views are one_level, physical and logical.
    The one_level view indicates data value is calculated by traversing only one
    level inside the module.
    Both physical view and logical view indicate data value is calculated by
    traversing through all levels of the hierarchical tree in the module. The
    difference between physical view and logical view is that in physical view
    soft macros inside the module will be traversed down.
    Plan groups only have logical view so if you specify a plan group in the
    option -module, this option will be ignored.
    The default value of this option is one_level.

-quiet
    Indicates that all error and warning messages are not to be reported.
```

DESCRIPTION

The **report_floorplan_data** command generates a report of floorplan data on the specified objects.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports floorplan data on cell I_ORCA_TOP in one_level view:

```
prompt> report_floorplan_data -module [get_cell I_ORCA_TOP] -view one_level
```

```
*****
Report : Floorplan Data
LIBRARY: lib_ORCA
DESIGN : ORCA
CELVIEW : ORCA
Date   : Mon Dec 17 05:49:04 2007
*****
```

Object	Module Type	View	FP Data Name	Value

I_ORCA_TOP	child_cell	one_level	hard_macro_area_percentage	0.000000
I_ORCA_TOP	child_cell	one_level	macro_area_percentage	0.501060
I_ORCA_TOP	child_cell	one_level	number_of_black_box	0
I_ORCA_TOP	child_cell	one_level	number_of_hard_macro	0
I_ORCA_TOP	child_cell	one_level	number_of_io_cell	0
I_ORCA_TOP	child_cell	one_level	number_of_macro	3
I_ORCA_TOP	child_cell	one_level	number_of_standard_cell	127
I_ORCA_TOP	child_cell	one_level	physical_area	1045885.445100

The following example reports floorplan data on current Milkyway design in physical view:

```
prompt> report_floorplan_data -module [current_mw_cel] -view physical
```

```
*****
Report : Floorplan Data
LIBRARY: lib_ORCA
DESIGN : ORCA
CELVIEW : ORCA
Date   : Mon Dec 17 05:50:38 2007
*****
```

Object	Module Type	View	FP Data Name	Value

ORCA	top	physical	hard_macro_area_percentage	0.151072
ORCA	top	physical	macro_area_percentage	0.535885
ORCA	top	physical	number_of_black_box	0
ORCA	top	physical	number_of_hard_macro	41
ORCA	top	physical	number_of_io_cell	924
ORCA	top	physical	number_of_macro	41
ORCA	top	physical	number_of_standard_cell	54092
ORCA	top	physical	physical_area	1690459.156600

SEE ALSO

`floorplan_data_attributes(3)`

`list_floorplan_data(2)`

report_fp_clock_plan_options

Reports options for the clock planning clock tree synthesis engine.

SYNTAX

```
status report_fp_clock_plan_options
```

ARGUMENTS

The **report_fp_clock_plan_options** command has no arguments.

DESCRIPTION

This command reports the options set by the **set_fp_clock_plan_options** command. If no clock plan options have been set, the command reports the default values. If you do not specify any options with this command, all settings are reported. The generated report can be redirected to an output file.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLE

The following example reports the directory used for clock planning constraint, log, and report files.

```
prompt> report_fp_clock_plan_options -output_directory
```

The following example redirects the report to the cp_options.log file.

```
prompt> report_fp_clock_plan_options > cp_options.log
```

SEE ALSO

```
compile_fp_clock_plan(2)  
set_fp_clock_plan_options(2)
```

report_fp_macro_array

Report user defined macro array constraints.

SYNTAX

```
status report_fp_macro_array
[-output_file file_name]
[array_name]
```

Data Types

<i>file_name</i>	string
<i>array_name</i>	string

ARGUMENTS

-output_file *file_name*

Specifies name of the file to write command output to. The default is to output to xterm and gui log window.

array_name

This option specifies the name of the macro array to be reported. The default is to report all the macro array constraints.

DESCRIPTION

The **report_fp_macro_array** command reports user defined macro array constraints set by **set_fp_macro_array** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to report the array constraint named arr1.

```
prompt>report_fp_macro_array arr1
```

SEE ALSO

set_fp_macro_array(2)
create_fp_placement(2)

report_fp_macro_options

Issues a report about the floorplan macro options.

SYNTAX

```
status report_fp_macro_options
[-output_file file_name]
[macro_cells]
```

Data Types

<i>file_name</i>	string
<i>macro_cells</i>	collection

ARGUMENTS

-output_file *file_name*

Specifies name of the file to write command output to. The default is to output to xterm and gui log window.

macro_cells

Reports floorplan macro options for the specified macros. The default is to report macro options for all macros.

DESCRIPTION

This command reports various options set by the **set_fp_macro_options** command to constrain macros during the automatic generation of the floorplan, using virtual flat placer in design planning.

For more information about these floorplan options, read the man page description of the **set_fp_macro_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows a sample report:

```
prompt> report_fp_macro_options
*****
Report macro options
Design: my_top_design
Version: Z-2007.03-ICC-SP3-INTERNAL
Date : Mon Jun 18 14:08:55 2007
*****
Pin Align:
```

Pin D[0] on cell A1 to align with port PD[0] of the design

Anchor Bound:

Anchor bound to 1 with x_offset=10.000 on cell(s):

A1

A2

A3

Info: 2 macro options reported.

1

SEE ALSO

`set_fp_macro_options(2)`
`create_fp_placement(2)`

report_fp_pin_constraints

Displays the pin assignment options that have been set for the specified soft macros, plan groups or ports.

SYNTAX

```
int report_fp_pin_constraints
[blocks]
[-block_level]
```

Data Types

blocks collection or list

ARGUMENTS

blocks

Specifies the soft macros and or plan groups for which the pin constraints are shown. If you do not specify this argument, the pin constraints are shown for all soft macros and plan groups in the current design.

-block_level

Reports the block-level pin assignment constraints on the currently open cell instead of the pin constraints for blocks contained in the cell.

DESCRIPTION

Displays the pin assignment options controlling both pin assignment and pin cutting.

Regarding side number, the left most edge is numbered 1 (one). Other edges are numbered according to their orders of traversal in the clockwise direction starting from edge 1. If there are multiple left most edges then edge 1 is the lowest leftmost edge.

Use **set_fp_pin_constraints** to set these pin constraints.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLE

The following example shows the pin constraints for all soft macros and plan groups in the current design.

```
prompt> report_fp_pin_constraints
```

SEE ALSO

`analyze_fp_routing(2)`

report_fp_placement

Generates a quality of results (QoR) report for virtual flat placement.

SYNTAX

```
int report_fp_placement
[-check_abutment]
[-verbose integer]
```

ARGUMENTS

-check_abutment

Select this option for channel-less design when you want to check for the abutment of each soft/hard macro with surrounding macro cell instances. The abutment check reports gaps detected between the macro cell instances. (No warning is issued if an edge of a soft/hard macro touches a cell boundary.)

-verbose *integer*

Enables you to define the amount of information to print. The default is 5.

DESCRIPTION

Generates a placement report to indicate the quality of placement. In this report the abbreviation "TL" means top level, the abbreviation "PG" means plan group. Note that in this context, plan group actually means any exclusive placement constraint so it includes voltage area constraints.

By default, this command will check for placement density and overlaps. When "-check_abutment" is specified, it will only check for the abutment of each soft and hard macro.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLE

The following example shows a basic output of the report_fp_placement command.

```
prompt> report_fp_placement
```

```
*****
Report      : Virtual Flat Placement

```

SEE ALSO

report_fp_placement_strategy

Prints the current values and default values for the parameters controlled by **set_fp_placement_strategy**.

SYNTAX

```
status report_fp_placement_strategy
```

ARGUMENTS

The **report_fp_placement_strategy** command has no arguments.

DESCRIPTION

Prints the current values and default values for the parameters controlled by **set_fp_placement_strategy**. These parameters are used to control the virtual flat placer and legalizer (**create_fp_placement** and **legalize_fp_placement**). These parameters are not applicable to other ICC placement commands or in other parts of the flow.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLE

The following example shows a sample output of the **report_fp_placement_strategy** command.

report_fp_rail_constraints

Reports power network synthesis (PNS) constraints defined by the user or by default.

SYNTAX

```
status report_fp_rail_constraints
[-all]
[-layer layer]
[-ring]
[-global]
[-block_ring block]
```

Data Types

<i>layer</i>	string
<i>block</i>	string

ARGUMENTS

-all

Report all the PNS constraints specified by the user or by default. This option is on by default.

-layer layer

Report the PNS layer constraints on the specified metal layer. The keyword "all" can be used as layer name to refers to all the metal layers. By default this option is off.

-ring

Report the core ring constraints specified by the user or by default. By default, this option is off.

-global

Report the global constraints specified by the users or by default. By default, this option is off.

-block_ring block

Report the block ring constraints on the specified block. The keyword "all" can be used as block name to refer to all blocks in the design. By default, this option is off.

DESCRIPTION

This command reports the power network synthesis (PNS) constraints for power planning including layer constraints, core ring constraints, block ring constraints and global constraints.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to report the constraints of the METAL5 layer.

```
prompt> report_fp_rail_constraints -layer METAL5
```

SEE ALSO

```
set_fp_rail_constraints(2)  
set_fp_block_ring_constraints(2)
```

report_fp_rail_strategy

Reports the user-defined strategy in power network synthesis (PNS) and power network analysis (PNA) strategies.

SYNTAX

```
status report_fp_rail_strategy
[-all]
[-use_lm_view]
[-use_tluplus]
[-pna_ultra_solver]
[-virtual_pad_wire_width]
[-define_pad_connection]
[-pad_resistance_file]
[-pns_skip_ir]
[-honor_macro_strap_config]
[-pns_hor_relative_offset]
[-pns_ver_relative_offset]
[-pns_ignore_via_cut_to_edge]
[-pns_ignore_soft_macro_blockage]
[-pns_clip_top_boundaries]
[-cut_plangroup_edge_layers]
[-pna_via_cut_row_column]
[-honor_macro_route_constraints]
[-align_strap_with_top_pin ]
[-align_strap_with_mtcmos_cells]
[-align_strap_with_bump_cells]
[-align_strap_with_m1_rail]
[-put_strap_in_std_cell_row]
```

ARGUMENTS

```
-use_lm_view
    Reports strategy value for the LM view set by using the -refdb_lm option of
    the set_fp_rail_strategy command. Please note that LM views are optional
    aspects of a Milkyway database. All ICC related Milkyway libraries may not
    have LM views present.

-use_tluplus
    Reports the strategy value for the TLU+ model set by using the -use_tluplus
    option of the set_fp_rail_strategy command.

-pna_ultra_solver
    Reports the strategy value for the ultra-solver set by using the -
    pna_ultra_solver option of the set_fp_rail_strategy command.

-virtual_pad_wire_width
    Reports the strategy value for the virtual wire width set by using the -
    virtual_pad_wire_width option of the set_fp_rail_strategy command.

-pad_resistance_file
    Reports the strategy value for the pad resistance file set by using the -
```

pad_resistance_file option of the **set_fp_rail_strategy** command.

-pns_skip_ir
 Reports strategy value for the IR drop simulation set by using the -
pns_skip_ir option of the **set_fp_rail_strategy** command.

-honor_macro_strap_config
 Reports the strategy value for the configuration file set by using the -
honor_macro_strap_config option of the **set_fp_rail_strategy** command.

-pns_hor_relative_offset
 Reports the strategy value for the relative offsets from the top-most
 horizontal layer to the specified layer set by using the -
pns_hor_relative_offset option of the **set_fp_rail_strategy** command.

-pns_ver_relative_offset
 Reports the strategy value for the relative offsets from the top-most
 vertical layer to the specified layer set by using the -
pns_ver_relative_offset option of the **set_fp_rail_strategy** command.

-pns_ignore_via_cut_to_edge
 Reports the strategy value set by using the **-pns_ignore_via_cut_to_edge**
 option of the **set_fp_rail_strategy** command.

-pns_ignore_soft_macro_blockage
 Reports the strategy value for soft macro blockages set by using the -
pns_ignore_soft_macro_blockage option of the **set_fp_rail_strategy** command.

-pns_clip_top_boundaries
 Reports the strategy value for clipping at top-cell boundaries set by using
 the **-pns_clip_top_boundaries** option of the **set_fp_rail_strategy** command.

-cut_plangroup_edge_layers
 Reports the strategy value for the synthesized strap overlap with plangroup
 edges set by using the **-cut_plangroup_edge_layers** option of the
set_fp_rail_strategy command.

-pna_via_cut_row_column
 Reports the strategy value for breaking a large square or a rectangular via
 array into smaller square via arrays based on the value set by using the -
pna_via_cut_row_column option of the **set_fp_rail_strategy** command.

-honor_macro_route_constraints
 Reports the strategy value for routing constraints for macros in an input
 file set by using the **-honor_macro_route_constraints** option of the
set_fp_rail_strategy command.

-align_strap_with_top_pin
 Reports the strategy value for PNS aligning synthesized P/G straps with P/G
 pins on block boundaries set by using the **-align_strap_with_top_pin** option
 of the **set_fp_rail_strategy** command.

-align_strap_with_mtcmos_cells
 Reports the strategy value for PNS generating P/G straps to align MTCMOS cells
 and connect the straps to corresponding pins in the MTCMOS cells based set

by using the **-align_strap_with_mtcmos_cells** option of the **set_fp_rail_strategy** command.

-align_strap_with_bump_cells
Reports the strategy value for specifying the direction and metal layer of straps to be aligned with bump cells in flip-chip design set by using the **-align_strap_with_bump_cells** option of the **set_fp_rail_strategy** command.

-align_strap_with_m1_rail
Reports the strategy value for PNS generating the lowest horizontal P/G straps to align with standard cell rails set by using the **-align_strap_with_m1_rail** option of the **set_fp_rail_strategy** command.

-put_strap_in_std_cell_row
Reports the strategy value for PNS generating the lowest horizontal P/G straps inside standard cell rows and between standard cell rails set by using the **-put_strap_in_std_cell_row** option of the **set_fp_rail_strategy** command.

DESCRIPTION

This command prints the current values of the strategies set by the **set_fp_rail_strategy** command. These strategies are used for power network synthesis and analysis.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example prints the current values of **-use_lm_view**.

```
prompt> report_fp_rail_strategy -use_lm_view\  
-use_lm_view = true
```

SEE ALSO

`set_fp_rail_strategy(2)`

report_fp_rail_voltage_area_constraints

Reports multi-voltage power network synthesis (MVDD PNS) constraints defined by the user or by default.

SYNTAX

```
status report_fp_rail_voltage_area_constraints
-all
-voltage_area voltage_area
[-synthesis]
[-layer layer]
[-ring]
[-global]
```

Data Types

<i>voltage_area</i>	string
<i>layer</i>	string

ARGUMENTS

```
-all
    Reports all voltage-area PNS constraints in all voltage areas. The -all and -voltage_area options are mutually exclusive; use only one.

-voltage_area voltage_area
    Reports all voltage-area PNS constraints in the specified voltage area. The -all and -voltage_area options are mutually exclusive; use only one.

-synthesis
    Reports synthesis PNS constraints in the voltage area. This includes net name(s), supply voltage, power budget, target voltage drop, and the number of power straps extended out from the voltage area.

-layer layer
    Reports layer PNS constraints in the voltage area. You can substitute the layer name you want for layer or use the keyword all as a layer value to refer to all the metal layers.

-ring
    Reports voltage-area ring PNS constraints in the voltage area.

-global
    Reports global PNS constraints in the voltage area.
```

DESCRIPTION

This command reports the multi-voltage power network synthesis (MVDD PNS) constraints for power planning, including voltage area synthesis constraints, layer constraints, ring constraints, and global constraints.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to report all PNS constraints in the *MULTIPLIER* voltage area.

```
prompt> report_fp_rail_voltage_area_constraints\n-voltage_area MULTIPLIER
```

SEE ALSO

`set_fp_rail_voltage_area_constraints(2)`

report_fp_relative_location

Report macro relative location constraints.

SYNTAX

```
status report_fp_relative_location
[-output_file file_name]
[cells]
```

Data Types

<i>file_name</i>	string
<i>cells</i>	collection

ARGUMENTS

-output_file *file_name*

Specifies name of the file to write command output to. The default is to output to xterm and gui log window.

cells

This option specifies the collection of macro cells whose relative location constraints to be reported. The default is to report relative location constraints on all macro cells.

DESCRIPTION

The **report_fp_macro_relative_location** command reports macro relative location constraints set by `set_fp_relative_location`.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to report the relative location constraint on cell iRAM1.

```
prompt>report_fp_macro_relative_location \
[get_cells "iRAM1"]
```

SEE ALSO

`set_fp_relative_location(2)`
`remove_fp_relative_location(2)`
`create_fp_placement(2)`

report_fp_voltage_area_constraints

Displays the feedthrough options that have been set for the specified voltage areas.

SYNTAX

```
int report_fp_voltage_area_constraints
```

ARGUMENTS

The **report_fp_voltage_area_constraints** command has no arguments.

DESCRIPTION

Displays the options controlling feedthrough creation on voltage areas.

Use **set_fp_voltage_area_constraints** to set these feedthrough constraints.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLE

THe following example shows the feedthrough constraints for all voltage areas in the current design.

```
prompt> report_fp_voltage_area_constraints
```

SEE ALSO

```
analyze_fp_routing(2)
remove_fp_voltage_area_constraints(2)
route_global(2)
set_fp_voltage_area_constraints(2)
```

report_groute_options

Reports global router cell-persistent options, their current value, default value, range, type and a brief description.

SYNTAX

```
status report_groute_options
[-name ]
```

ARGUMENTS

-name name

Specifies the name or name pattern of the option to be reported. Name pattern will report all options that match it. By default, if "-name" is not specified, all groute options are reported.

DESCRIPTION

The **report_groute_options** command shows options that tune global router operation. These settings are persistent in the Milkyway design. Cell-persistent options are saved in cell data base by **set_groute_options** command. Before printing options, **report_groute_options** loads all groute options from currently opened cell. All options are optional. This command prints all available global router options, their current value, default value, range, type and a brief description. However, if you want to see a specific option or options that match a specified name pattern, use argument "-name". You can set global router options with command **set_groute_options**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> report_groute_options -name accessPolyPin
(Integer Option for "groute" "accessPolyPin" 1)
;;      range [0,1], default=1, stored in cell;
;;      0: don't access poly pins,
;;      1: access poly pins.
```

SEE ALSO

set_groute_options(2)

report_hierarchy

Displays the reference hierarchy of the current instance or the current design.

SYNTAX

```
integer report_hierarchy
[-nosplit]
[-full]
[-noleaf]
```

ARGUMENTS

-nosplit
Prevents line-splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-full
Displays the full hierarchy. By default, components of submodules in multiple locations in a hierarchy are listed only once. An ellipsis (...) indicates the contents of a previously-displayed module.

-noleaf
Indicates that the leaf library cells are to be excluded from the reference hierarchy report.

DESCRIPTION

This command displays the indented reference hierarchy of the current instance or the current design. If the current instance has been set, the report is generated for the design of that instance. Otherwise, the report is generated for the current design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example of a hierarchy report:

```
prompt> report_hierarchy
*****
Report : hierarchy
Design : CONTROL
Version: v2.0
```

Date : Fri Mar 20 14:09:24 1991

report_ideal_network

Displays information about ports, pins, nets, and cells on ideal networks in the current design.

SYNTAX

```
int report_ideal_network
[-net]
[-cell]
[-load_pin]
[-timing]
[object_list]
```

Data Types

object_list list

ARGUMENTS

-net

Causes **report_ideal_network** to list all nets in the specified ideal network(s). By default, nets are displayed for all ideal networks.

-cell

Indicates to display all cells in the specified ideal network(s). By default, cells are displayed for all ideal networks.

-load_pin

Specifies to display load pins (boundary pins) of the specified ideal network(s), along with any ideal timing set on them using the **set_ideal_latency** and **set_ideal_transition** commands. By default, load pins are displayed for all ideal networks.

-timing

Specifies to display all internal pins (for example, non-source and non-boundary pins) in the specified ideal network(s) that have ideal timing set on them using the **set_ideal_latency** and **set_ideal_transition** commands. By default, internal pins with timing are displayed for all ideal networks.

object_list

Defines a list of source ports or source pins of the specified ideal network(s) to be displayed. By default, the source pins and source ports for all ideal networks in the current design are displayed.

DESCRIPTION

Displays information about the ideal networks in the current design. If no arguments are specified, all ideal network sources in the current design are displayed. If you specify a list of source pins or ports, the command displays information about the ideal networks at these objects. By default, source pins, internal pins with ideal timing, load (boundary) pins, nets, and cells are displayed. You can force a subset

of this information to be displayed using the arguments listed above.

The "Latency" and "Transition" columns show the minimum and maximum values set for both rising and falling edges. You set these values with the **set_ideal_latency** and **set_ideal_transition** commands.

Ideal networks are an extension of ideal nets that incorporate automatic propagation of the **ideal** attribute. You specify only the source ports or pins of the network; all the nets, cells, and pins on the transitive fanin of these objects are treated as ideal by **compile**. The **ideal_network** attribute is automatically spread by Design Compiler, and respread as needed during **compile** optimizations.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows an ideal network report.

```
prompt> set_ideal_network {reset1 reset2}
prompt> set_ideal_latency 5.2 reset1
prompt> set_ideal_transition 0.6 reset1
prompt> report_ideal_network

report_ignored_layers

Reports the routing layers that are ignored during congestion analysis and RC estimation. If you have set the minimum and maximum routing layers for the design, they are also reported.

SYNTAX

```
status report_ignored_layers
```

ARGUMENTS

The **report_ignored_layers** command has no arguments.

DESCRIPTION

During congestion analysis and RC estimation, the tool can ignore some routing layers. Use this command to report the ignored layers. If you have specified the minimum and maximum routing layers for the design, these are also reported.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the **report_ignored_layers** command:

```
prompt> report_ignored_layers
```

SEE ALSO

```
remove_ignored_layers(2)  
report_lib(2)  
set_ignored_layers(2)
```

report_ilm

Reports information about the specified ILM instance.

SYNTAX

```
status report_ilm
[ilm_list]
```

Data Types

ilm_list list

ARGUMENTS

ilm_list

Specify the ILM instances to be reported. The option value can be a collection of ILM instances or name patterns.

The command fails if it cannot find any specified ILM instance.

If this option is not specified, the command reports all the ILM instances in the current design.

DESCRIPTION

The report_ilm command enables you to get detailed information about existing ILMs. If you specify the ILM, only those ILMs are reported; otherwise all ILMs in the current design are reported.

The information reported for each ILM includes: ILM reference name, ILM instance name, filepath of the library from which the ILM was loaded, date and time of ILM creation, options used for ILM creation, cell count and compression statistics for each of the ILM, cell count and compression statistics for the top design with ILMs, tlu plus settings, parasitics data of the ILM.

This command returns a 1 if successful and returns a 0 otherwise.

EXAMPLES

The following example reports about all ILMs in the current design.

```
prompt> report_ilm
*****

SEE ALSO

`create_ilm(2)`
`get_ilms(2)`

report_internal_loads

Displays internal loads on the nets in the current design.

SYNTAX

```
int report_internal_loads
[-nosplit]
```

ARGUMENTS

-nosplit

Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column. This option prevents line-splitting and facilitates writing software to extract information from the report output.

DESCRIPTION

Displays all internal loads specified on nets with the **set_load** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following is an example of the internal-loads report:

```
prompt> report_internal_loads
```

```
*****
Report : internal_loads
Design : comb_internal
Version: v2.0
Date   : Fri Nov 30 12:44:23 1990
*****
```

Attributes:

p - includes pin load

Net	Load	Attributes
n1	3.0000	p
n2	4.5000	

SEE ALSO

`report_design(2)`
`set_load(2)`

report_io_constraints

Displays a report of the pin and pad physical constraints.

SYNTAX

```
status report_io_constraints
[-cell name]
[-pin_only]
[-pad_only]
[-chiplevel_pad_only]
[objects]
```

Data Types

<i>name</i>	string
<i>objects</i>	collection

ARGUMENTS

-cell *name*

Specifies the Milkyway cell name or plan group whose physical constraints are reported. The default behavior is to report the current cell's physical constraints.

-pin_only

Reports only pin physical constraints. The **-pin_only**, **-pad_only** and **chiplevel_pad_only** options are mutually exclusive. Use only one.

-pad_only

Reports only pad physical constraints. The **-pin_only**, **-pad_only** and **chiplevel_pad_only** options are mutually exclusive. Use only one.

-chiplevel_pad_only

Reports only chip-level pad physical constraints. The **-pin_only**, **-pad_only** and **chiplevel_pad_only** options are mutually exclusive. Use only one.

objects

Specifies the pin or pad for which the physical constraints are displayed. If this option is not specified, the physical constraints for all pins, pads and chip level pads are reported.

DESCRIPTION

This command allows you to display a report of the pin and pad physical constraints that were set by using the **set_pin_physical_constraints**, **set_pad_physical_constraints**, **set_chiplevel_pad_physical_constraints** or **read_io_constraints** commands.

If no option is specified, the command displays a report of all the physical constraints for all pins, pads and chip level pads.

For the layer constraint, the **report_io_constraints** command displays the layer mask name.

EXAMPLES

The following example displays the physical constraints for all pins, pads and chip level pads in the current design.

```
prompt> report_io_constraints
```

The following example displays the physical constraints for all pins.

```
prompt> report_io_constraints -pin_only
```

SEE ALSO

report_isolate_ports

Displays the status of port isolation on ports on which isolation was requested.

SYNTAX

```
int report_isolate_ports  
[-nosplit]
```

ARGUMENTS

-nosplit

Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line in the same column. This option prevents line-splitting and facilitates writing software to extract information from the report output.

DESCRIPTION

The **report_isolate_ports** command displays all the ports on which isolation was requested and on which isolation cells were inserted.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example of the report that is generated when you execute the **report_isolate_ports** command:

```
prompt> report_isolate_ports
```

```
report_isolate_ports
```

```
***** Report : isolate_ports Design : pil
Version: 2001.08 Date : Mon Apr 23 15:05:21 2001
*****

report_isolate_ports

1750

report_isolated_via

Reports isolated via violations.

SYNTAX

```
integer report_isolated_via
[-isolated_via_spacing distance]
[-isolated_via_quadrant_spacing distance]
```

Data Types

distance distance

ARGUMENTS

-isolated_via_spacing *distance*

Determines the adjacent via spacing, in microns, that triggers isolated via violation. If there is no adjacent via located less than n microns from the via, the violation of type "Isolated Via" is reported. If set, this argument will be stored in a "droute" cell parameter "isolatedViaSpacing". The range is 0.0 to 20.0. The default is the value, set in a "droute" cell parameter "isolatedViaSpacing", which in turn has a default of 1.0.

To set a distance in a "droute" cell parameter "isolatedViaSpacing", use
set_parameter -type real -module droute \
 -name isolatedViaSpacing -value n

-isolated_via_quadrant_spacing *distance*

Determines the adjacent via spacing, in microns, in four quadrants. If adjacent vias that cover all four quadrants are not located less than n microns from the via, the violation of type "Isolated Via" is reported. If set, this argument will be stored in a "droute" cell parameter "isolatedViaQuadrantSpacing". The range is 0.0 to 50.0. The default is the value, set in a "droute" cell parameter "isolatedViaQuadrantSpacing", which in turn has a default of 10.0.

To set a distance in a "droute" cell parameter "isolatedViaQuadrantSpacing", use

```
set_parameter -type real -module droute \
                  -name isolatedViaQuadrantSpacing -value n
```

DESCRIPTION

This command is used to report isolated vias rule violations. If two vias are not aligned, corner-to-corner spacing is measured for *isolated_via_spacing* and *isolated_via_quadrant_spacing*. If two vias are aligned, edge-to-edge spacing is measured for *isolated_via_spacing* and *isolated_via_quadrant_spacing*. This command will check *isolated_via_spacing* first, and then *isolated_via_quadrant_spacing*. The value of *isolated_via_quadrant_spacing* should be greater than *isolated_via_spacing*. Please be advised that greater values affect the speed of command execution.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports isolated vias rule violations for adjacent vias that are located less than 5.0 microns from the via (isolated_via_quadrant_spacing is 10.0 by default):

```
prompt> report_isolated_via -isolated_via_spacing 5.0
```

APPENDIX

The following settings stored in "drouite" cell parameters, and set in command **set_parameter**, will control defaults and operation of **report_isolated_via** command:

Common for all via layers parameters:

"isolatedViaSpacing" and "isolatedViaQuadrantSpacing".

The range for "**isolatedViaSpacing**" is 0.0 to 20.0. The default is 1.0. The range for "**isolatedViaQuadrantSpacing**" is 0.0 to 50.0. The default is 10.0.

To set these parameters, use:

```
set_parameter -type real -module drouite \
              -name isolatedViaSpacing -value n
set_parameter -type real -module drouite \
              -name isolatedViaQuadrantSpacing -value n
```

To report isolated via violations on specified via layers only, the following settings should be set with command **set_parameter**:

"checkIsolatedViaPerLayer" - if this parameter is set, the rule is applied only to cut layers, which have "per-layer" isolated via spacing set, and if it is not set, the rule is applied to all cut layers. Valid values are 0 (which is the default) and 1. If it is set to 1, the values of common for all via layers parameters "**isolatedViaSpacing**" and "**isolatedViaQuadrantSpacing**" are ignored. The arguments to **report_isolated_via** command that also can set these common parameters, -isolated_via_spacing and -isolated_via_quadrant_spacing, are also ignored.

To set or reset this run-time integer parameter, use:

```
set_parameter -type int -module drouite \
              -name checkIsolatedViaPerLayer -value n
```

To set "per-layer" isolated via spacing and isolated via quadrant spacing, use the following real parameters:

```
set_parameter -type real -module drouite \
              -name polyContIsolatedViaSpacing -value n
set_parameter -type real -module drouite \
```

```

        -name via1IsolatedViaSpacing -value n
set_parameter -type real -module droute \
        -name via2IsolatedViaSpacing -value n
set_parameter -type real -module droute \
        -name via3IsolatedViaSpacing -value n
set_parameter -type real -module droute \
        -name via4IsolatedViaSpacing -value n
set_parameter -type real -module droute \
        -name via5IsolatedViaSpacing -value n
set_parameter -type real -module droute \
        -name via6IsolatedViaSpacing -value n
set_parameter -type real -module droute \
        -name via7IsolatedViaSpacing -value n
set_parameter -type real -module droute \
        -name via8IsolatedViaSpacing -value n
set_parameter -type real -module droute \
        -name via9IsolatedViaSpacing -value n
set_parameter -type real -module droute \
        -name via10IsolatedViaSpacing -value n
set_parameter -type real -module droute \
        -name via11IsolatedViaSpacing -value n

set_parameter -type real -module droute \
        -name polyContIsolatedViaQuadrantSpacing -value n
set_parameter -type real -module droute \
        -name via1IsolatedViaQuadrantSpacing -value n
set_parameter -type real -module droute \
        -name via2IsolatedViaQuadrantSpacing -value n
set_parameter -type real -module droute \
        -name via3IsolatedViaQuadrantSpacing -value n
set_parameter -type real -module droute \
        -name via4IsolatedViaQuadrantSpacing -value n
set_parameter -type real -module droute \
        -name via5IsolatedViaQuadrantSpacing -value n
set_parameter -type real -module droute \
        -name via6IsolatedViaQuadrantSpacing -value n
set_parameter -type real -module droute \
        -name via7IsolatedViaQuadrantSpacing -value n
set_parameter -type real -module droute \
        -name via8IsolatedViaQuadrantSpacing -value n
set_parameter -type real -module droute \
        -name via9IsolatedViaQuadrantSpacing -value n
set_parameter -type real -module droute \
        -name via10IsolatedViaQuadrantSpacing -value n
set_parameter -type real -module droute \
        -name via11IsolatedViaQuadrantSpacing -value n

```

The range for "per-layer" isolated via spacing is 0, 20.0; the default is 0.0, which disables processing isolated via rule on the specified via layer. The range for "per-layer" isolated via quadrant spacing is 0, 50.0; the default is 0.0, which disables processing isolated via quadrant rule on the specified via layer.

report_isolated_via
1754

report_isolation_cell

Displays information about isolation cells in the current scope. This command is supported only in UPF mode.

SYNTAX

```
status report_isolation_cell
[isolation_cells]
[-domain power_domains]
[-verbose]
[-port a_list_of_ports,_port_instances_or_hierarchy_ports]
[-strategy a_list_of_isolation_strategies]
```

Data Types

<i>isolation_cells</i>	list
<i>power_domains</i>	list

ARGUMENTS

isolation_cells
Specifies the isolation cells that are to be reported. If the specified supply cells do not exist in the current scope, the command fails.
By default, all isolation cells in the current scope are reported.

-domain power_domains
Specifies the power domains on which to report all isolation cells. If the power domains specified do not exist in the current scope, the command fails.

-verbose
Reports the isolation strategy information in addition to the isolation cells information.

DESCRIPTION

The *report_isolation_cell* command enables you to get detailed information about all isolation cells within the current scope. If the **-domain** option is specified, all isolation cells in the specified domains are reported. If the **-strategy** option is specified, all isolation cells under the specified strategy for the given power domain are reported.

By default, the report displays the following information:

- The name of the port and pin isolated by the isolation cell
- The direction of the port
- The instance name of the isolation cell
- The library reference cell name of the isolation cell.

If you specify the **-verbose** option, the report also displays details of the isolation strategy:

- The name of the isolation strategy
- The location of the cell dictated by the strategy
- The enable signal
- The sense value
- The clamp value
- The elements to which the strategy applies
- The No Isolation information
- The power and ground nets of the strategy.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports on all of the isolation cells in the current scope:

```
prompt> report_isolation_cell

report_keepout_margin

Reports keepout margins of a specified type for the specified cells in the design.

SYNTAX

```
int report_keepout_margin
[-type hard | soft]
[-original]
[-parameters]
[-all_derivable]
[object_list]
```

Data Types

object_list list

ARGUMENTS

-type hard | soft

Specifies the type of keepout to be reported. The valid values are **hard** or **soft**. By default, keepouts of both soft and hard types are reported for the cells or library cells.

-original

Reports the original keepout margin values which are set using set_keepout_margin command and orientation of the cell when the keepout margin is set on the cell.

-parameters

Reports the following pin count based parameter values. 1. tracks_per_macro_pin 2. min_padding_per_macro 3. max_padding_per_macro

-all_derivable

Reports all the derivable keepout margin values for the cells specified in the object list. Keepout margin values set on the cells, derivable from the lib cells and pin count based values in case of macros.

object_list

Describes the list of cells or library cells for which keepouts are to be reported. Keepouts are reported for all cells with FIXED_PLACEMENT or library cells in specified in *object_list*.

DESCRIPTION

This command reports keepouts for the specified cells or library cells. If no hard or soft keepout exists the specified cell or library cell, and this command is called to report on it, a warning message is printed out and no action is taken. This command prints out the margin parameters for a keepout. These are of the form {left_x, bottom_y, right_x, top_y}. All units are in microns.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports hard keepouts for cells in an object list named *MY_CELL*.

```
prompt> report_keepout_margin -type hard MY_CELL
```

The following example reports hard keepouts for library cells in an object list named *MY_LIB_CELL*.

```
prompt> report_keepout_margin -type hard MY_LIB_CELL
```

The following example reports the original hard keepout margin values set on the cell in object list named *MY_CELL*.

```
prompt> report_keepout_margin -type hard MY_CELL -original
```

The following example reports all the pin count based parameters which will be used during the calculation of pin count based keepout margins for macro cells

```
prompt> report_keepout_margin -parameters
```

The following example reports all the derivable keepout margin values for the cells in object_list named *MY_CELL*

```
prompt> report_keepout_margin MY_CELL -all_derivable
```

SEE ALSO

`remove_keepout_margin(2)`

report_latency_adjustment_options

Reports the options for I/O latency adjustment, defined by using the **set_latency_adjustment_options** command.

SYNTAX

```
status report_latency_adjustment_options
```

DESCRIPTION

This command reports the I/O latency adjustment options set earlier by using the **set_latency_adjustment_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports I/O latency adjustment options.

```
prompt> report_latency_adjustment_options
```

SEE ALSO

`set_latency_adjustment_options(2)`

report_lcc_hotspot

Reports lithography compliance check (LCC) hotspots.

SYNTAX

```
status report_lcc_hotspot
[-sort_by_attribute layer | level | type]
```

ARGUMENTS

-sort_by_attribute layer | level | type
Specifies by which attribute the hotspots will be sorted and output.
By default, the hotspots are sorted by layer.

DESCRIPTION

This command reports the detected hotspots, which are sorted by the specified attribute (layer, level, or type).

You can use this command to output the hotspots in the order that you would like to browse or check.

For each of the reported hotspots, the report includes the following information: type, level, layer, and coordinates.

EXAMPLES

The following example reports the hotspots sorted by level:

```
prompt> report_lcc_hotspot -sort_by_attribute level
```

```

report_left_right_filler_rule

Prints out the left and right filler cell insertion rules.

SYNTAX

```
status report_left_right_filler_rule
```

DESCRIPTION

This command prints out the left and right filler rules of the current design. A left filler rule inserts a left filler cell to the immediate left side of a standard cell. A right filler rule inserts a right filler cell to the immediate right side of a standard cell. A left or right filler cell is often used to avoid certain design rule spacing problems.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

Here is an example of the output.

```
; Left/Right filler rules
set_left_right_filler_rule -left "fillAL" -right "fillAR"
-lib_cell {nd02d0 nr02d0} set_left_right_filler_rule -left "fillBL" -right "fillBR"
-lib_cell {bufbd1 dfnrq1}
```

SEE ALSO

```
insert_stdcell_filler(2)
set_left_right_filler_rule(2)
remove_left_right_filler_rule(2)
```

report_level_shifter

Displays information about level shifter cells in the current scope. This command is supported only in UPF mode.

SYNTAX

```
status report_level_shifter
[level_shifter_cells]
[-domain power_domains]
[-verbose]
[-nosplit]
```

Data Types

<i>level_shifter_cells</i>	list
<i>power_domains</i>	list

ARGUMENTS

level_shifter_cells

Specifies the level shifter cells that are to be reported. If the specified supply cells do not exist in the current scope, the command fails. By default, all level shifter cells in the current scope are reported.

-domain power_domains

Specifies the power domains to report all level shifter cells in the design belonging to the power domains. If the power domain specified does not exist in the current scope, the command fails. This argument is optional and can be used to report level shifter cells selectively.

-verbose

Reports the level shifter strategies along with the level shifter cells.

-nosplit

Prevents line-splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_level_shifter** command enables you to get detailed information about all level shifter cells in the current scope. If the **-domain** argument is specified, all level shifter cells in the specified domains are reported. The report consists of two or three parts, depending on whether or not the **-verbose** option is specified.

- The first part contains the level shifter summary check for a power domain. The summary reports the number of violating level shifter cells that are marked dont_touch and those that are not marked dont_touch. It also reports the total number of level shifter cells belonging to the power domain.

- If the **-verbose** option is specified, the second part of the report provides the details of the level shifter strategy. The details include the name, type, applies_to/elements, threshold voltage, location, and no shift of the strategy.
- The third part of the report shows the following information about the level shifter cells:
 - Name of the level shifter cell
 - Reference name
 - Input and output power net and ground net information, including name and voltage
 - Main power and ground net name and direction
 - Whether or not there is a violation and the reason for the violation
 - Input and output ranges of the level shifter. Only one range is reported if the input and output ranges are the same.
 - Type of level shifter.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example reports the information about all level shifter cells in the current scope:

```
prompt> report_level_shifter
```

```

report_lib

Displays information about technology, symbol libraries, or physical libraries.

SYNTAX

```
int report_lib
[-all]
[-ccs_recv]
[-em]
[-fpga]
[-full_table]
[-k_factors]
[-power]
[-power_label]
[-routing_rule]
[-rwm]
[-table]
[-timing]
[-timing_arcs]
[-timing_label]
[-user_defined_data]
[-vhdl_name]
[-yield]
[-switch]
[-pg_pin]
[-char]
[-operating_condition]
[-op_cond_name op_cond_name]
[cell_list]
library_name
```

Data Types

<i>cell_list</i>	string
<i>library_name</i>	string

ARGUMENTS

-all

Lists all timing, power, electromigration, and FPGA related information. This option applies only to technology libraries.

-ccs_recv

Lists ccs/receiver information for library cells. This option applies only to technology libraries.

-em

Lists all electromigration related information. This option applies only to technology libraries.

-fpga

Lists FPGA library related information. This option applies only to FPGA

libraries.

-full_table
Lists each cell's state table description in tabular, expanded form. This option applies only to technology libraries.

-k_factors
Lists scaling information for library cells. This option applies only to technology libraries.

-power
Lists all power-related information. This option applies only to technology libraries.

-power_label
Lists all power label related information. This option applies only to technology libraries.

-routing_rule
Lists nondefault routing rule information from physical libraries. This option applies only to physical libraries.

-rwm
Lists routing wire model information from physical libraries. This option applies only to physical libraries. In a routing wire model report, the original routing wire model is printed out, which includes overlap wire ratio, adjacent wire ratio, wire ratio and wire length of both directions. Also reported is capacitance (in database units) per micron for each layer and for each direction (based on each layer's wire ratio), based on the default operating condition. The report shows resistance per square (in database units) for each direction based on the default operating condition. These derived numbers provide useful information before applying the routing wire model using the **set_routing_wire_model** command.

-table
Lists cells' state table description in compact form. This option applies only to technology libraries.

-timing
Lists all timing-related information. This option applies only to technology libraries.

-timing_arcs
Lists all cell timing arcs. This option applies only to technology libraries.

-timing_label
Lists all timing label related information. This option applies only to technology libraries.

-user_defined_data
Lists user-defined groups and attributes information. This option applies to both technology and physical libraries.

-vhdl_name
Lists changed VHDL names at the end of the report. This option applies only

to technology libraries.

-yield
Lists failure rate information for library cells. This option applies only to technology libraries.

-switch
Lists pin switch function info and cell level steady state current info. The switch function of a pg pin should use "-pg_pin" to display. This option applies only to technology libraries.

-pg_pin
Lists pg_pin information, such as pg pin definition and the voltage name to which a signal pin has been linked to and pg type. This option applies only to technology libraries.

-char
Lists cell characterization information, such as sensitization and pre-driver model. This option applies only to technology libraries.

-operating_condition
Lists all library operating condition information, when there is only this option selected, report_lib only report operating condition info, no other information reported.

-op_cond_name op_cond_name
Lists operating condition information by name, when there is only this option selected, report_lib only report operating condition info, no other information reported.

cell_list
Specifies a list of cells about which information is to be reported. The default is to report information about all cells in the technology or physical library. This option applies only to technology and physical libraries.

library_name
Specifies the name of the library to report. This argument is required, so if not specified, an error is returned.

DESCRIPTION

The **report_lib** command displays information about technology, physical, or symbol libraries.

A technology library report displays a list of operating conditions, timing ranges, and wire load models. The **-timing** option lists all detailed timing-related information in the library. The **-noise** option lists all detailed noise-related information in the library. The **-power** option lists all detailed power-related information in the library. The **-em** option lists all detailed electromigration-related information in the library.

The **-timing_arcs** option lists timing arcs in the library. The **-noise_arcs** option lists noise arcs in the library. The **-vhdl_name** option lists the cells and ports whose database (.db) names are different from their VHDL names. The **-table** option

lists the state table information for each cell in a very compact form. The **-full_table** option lists the state table information for each cell in a tabular form. The **-timing_label** option lists the timing labels for all timing arcs, if specified, in a tabular form. The **-power_label** option lists the power labels for all power arcs if specified by the user in a tabular form. The **-fpga** option lists all detailed FPGA-related information, such as parts and I/O cell attributes, in the library. The **-user_defined_data** option lists all detailed information on the user-defined groups and attributes. The **-switch** option lists pin switch function info and cell level steady state current info. The **-pg_pin** option lists pg_pin information. The **-char** option lists cell characterization information. The **-operating_condition** or **-op_cond_name <op_cond_name>** option lists library operating condition information. The **-all** option lists all detailed timing-related, power-related, electromigration-related, and fpga-related information in the library. If a **cell_list** is specified with **report_lib**, the report includes only the specified cells; otherwise all cells in the given technology library are listed, with annotations showing the attributes specified for them.

The **-timing**, **-noise**, **-table**, **-full_table**, **-timing_label**, **-power_label**, **-em**, **-power**, **-yield**, **-pg_pin** and **-switch** options can be used only with a technology library read in from a library source (lib) file. If the library is read in from a database (.db) file, an error message is issued.

A physical library report displays a list of available layers, a list of vias, a list of sites and a list of cells. If a **cell_list** is specified with **report_lib**, the report includes only the specified cells; otherwise all cells in the given physical library are listed.

A symbol library report displays a list of the names of symbol definitions contained in the library **library_name**. It also reports the route grid and meter scale for the library.

Any library object added using the **update_lib** command is marked with an asterisk (*) following its name, to identify those objects that have been added since the initial library was created with the **read_lib** command.

To generate a report, the specified library must be loaded into dc_shell or lc_shell, unless it is found in the **search_path**. The command **list_libs** displays the libraries that are currently loaded.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

For details about library electromigration report contents and syntax, see the *Library Compiler Reference Manual*.

The following command generates a report on timing arcs in the **tech_lib** library. The `INV_NEW` cell is identified as having been added using the **update_lib** command:

```
prompt> report_lib tech_lib -timing_arcs
```

Arc	Arc Pins
-----	----------

Cell	Attributes	#	Sense/type	From	To	When
AND		0	pos unate	A	Z	
		1	pos unate	B	Z	
INVERT		0	neg unate	A	Z	
INV_NEW		0	neg unate	A	Z	

If the **-timing_arcs** option is not used, the last five columns do not appear.

The following command generates a report for a technology library. This type of report includes names of the library cells, wire load models, timing ranges, and operating conditions, the date the library was created, and the date the library was generated.

```
prompt> report_lib tech_lib
```

The following command generates a report for a symbol library. The report includes names of all symbol definitions, the route_grid, and meter_scale:

```
prompt> report_lib sym_lib.sdb
```

The following command generates a report that displays timing arcs for the inverter cell from the **tech_lib** library:

```
prompt> report_lib tech_lib -timing_arcs inverter
```

The following example generates a report that displays noise arcs for the inverter cell from the **tech_lib** library:

```
prompt> report_lib tech_lib -noise_arcs inverter
```

The following is an example of a compact report on state table information in the **tech_lib** library:

```
prompt> report_lib tech_lib -table
```

State table descriptions:

CELL(D_LATCH) :

```
PIN(Q) : CD, D, G
        TABLE: HNLNLNL
END_PIN Q;
```

```
PIN(QN) :
STATE_FUNCTION: Q'
END_PIN QN;
END_CELL D_LATCH;
```

The following is an example of a tabular report on state table information in the **tech_lib** library:

```
prompt> report_lib tech_lib -full_table
```

State table descriptions:

```
CELL (D_LATCH) :
```

```
PIN(Q) : CD, D, G
```

```
TABLE:
```

000	L
001	L
010	L
011	L
100	N
101	L
110	N
111	H

```
END_PIN Q;
```

```
PIN(QN) :
```

```
STATE_FUNCTION: Q'
```

```
END_PIN QN;
```

```
END_CELL D_LATCH;
```

The following is an example of a pg_pin report in the **tech_lib** library:

```
prompt> report_lib tech_lib -pg_pin
```

```
CELL (LVLHLEHX2) :
```

```
PG_PIN(VDDI) :
```

```
VOLTAGE_NAME: VDDH  
PG_TYPE: primary_power  
END_PIN VDDI;
```

```
PG_PIN(VSS) :
```

```
VOLTAGE: VSS  
PG_TYPE: primary_ground  
END_PIN VSS;
```

```
PIN(QN) :
```

```
RELATED_POWER_PIN : VDDI  
RELATED_GROUND_PIN : VSS  
END_PIN QN;
```

```
END_CELL LVLHLEHX2;
```

The following is an example of a characterization report in the **tech_lib** library:

```
prompt> report_lib tech_lib -char
```

```

report_milkyway_version

Reports information for the specified cell, including the Milkyway data model version and revision information.

SYNTAX

```
status report_milkyway_version
[-cell cell_name | -all]
```

Data Types

cell_name string

ARGUMENTS

```
-cell cell_name
      Generates a report for the specified cell.

-all
      Generates a report for all cells in the current Milkyway design library.
```

DESCRIPTION

This command reports the following for each reported cell:

- The cell data model version
- The product version that is compatible with the cell data model version
- The product release version that created the initial design
- The cell's initial creation time
- The product release version that modified the design last
- The cell's last modification time

All cells must be closed when running this command.

Either the -cell or -all option must be specified. If neither option is specified, this command will display an error message and fail. If both options are specified, the -all option will take precedence and a report is generated for all cells.

EXAMPLES

The following example displays a report for the cell "top" in the current Milkyway design library.

```
prompt> open_mw_lib design
prompt> report_milkyway_version -cell top
```

Cell Name	top.CEL;2
Data Model	1.2
Compatible Product	A-2007.12 And Older Versions
Creator	Z-2007.03-ICC-SP2-1

```
Creation Time           Fri Jul 27 11:10:04 2007
Modifier                Z-2007.03-ICC-SP2-1
Modification Time       Mon Jul 30 17:34:34 2007
1
```

The following example displays a report for all cells in the current Milkyway design library.

```
prompt> open_mw_lib design
prompt> report_milkyway_version -all

Cell Name              top.CEL;1
Data Model              1.2
Compatible Product      A-2007.12 And Older Versions
Creator                 Z-2007.03-ICC-SP2-1

report_mim

Generates a report on the multiple instantiated modules (MIMs) in the design.

SYNTAX

```
status report_mim
```

DESCRIPTION

This command prints a report on all the multiple instantiated modules (MIMs) in the design. This report describes which plan groups or soft macros are MIMs plus additional information on their status. The additional infomation tells you what is the status of the copied placement data (from **copy_mim**) and also a suggested MIM plan group flipping grid. An MIM plan group flipping grid is a grid on which you can place an MIM plan group such that when it is flipped, the standard cells placement remains legal.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows sample output of the **report_mim** command.

```
prompt> report_mim
*****
Report : MIM
Design : orca.CEL;1
Version: B-2008.09-ICC
Date   : Fri Feb 15 10:32:44 2008
*****

Reference tarang is instantiated to:
    Plan Group: tarang1 (orientation N)
    Plan Group: tarang2 (orientation N)
    Plan Group: tarang3 (orientation N)
    Plan Group: tarang4 (orientation N)
    Reference tarang is instantiated 4 times.
Total 1 MIM reference and 4 MIM instances.
MIM plan group flipping grid: x offset=255.000, x step=0.560
                                y offset=255.000, y step=8.960
Copy_mim stored placement data...
MIM group #0: The copy source is tarang1, stored orientation: N
MIM group #0: A copy target is tarang2, stored orientation: N
MIM group #0: A copy target is tarang3, stored orientation: N
MIM group #0: A copy target is tarang4, stored orientation: N
MIM Report End
1
```

SEE ALSO

`copy_mim(2)`
`flip_mim(2)`

report_mode

Prints a report of the instance modes.

SYNTAX

```
string report_mode
[-nosplit]
[instance_list]
```

Data Types

instance_list list

ARGUMENTS

-nosplit
Prevents line-splitting and facilitates writing software to extract information from the report output. By default, most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

instance_list
Indicates that the mode report is to include only the specified cells. By default, all cells that have modes are included.

DESCRIPTION

Reports which cells have modes and, for each mode, specifies that the mode is currently enabled or disabled. This reports reflects the mode specifications of the **set_mode** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example reports that 2 cells in the design have modes: cell Uram1, and cell Uram2.

```
prompt> report_mode
*****
Report : mode
Design : top_design
*****
```

Cell	Mode (Group)	Status
Uram1/core (RAM2_core)	read(rw) write(rw)	ENABLED ENABLED
Uram2/core (RAM2_core)	read(rw) write(rw)	ENABLED ENABLED

The following example reports that modes are specified for the 2 RAMs that have mode in the design. Ram Uram1 is set in mode read, and Ram Uram2 is set in mode write. This means all timing arcs of RAM Uram1 associated with mode read are enabled, and all timing arcs associated with mode write are disabled.

```
prompt> set_mode read Uram1/core
prompt> set_mode write Uram2/core
prompt> report_mode
```

```
*****
Report : mode
Design : top_design
*****
```

Cell	Mode (Group)	Status
Uram1/core (RAM2_core)	read(rw) write(rw)	ENABLED disabled
Uram2/core (RAM2_core)	read(rw) write(rw)	disabled ENABLED

report_mpc_macro_array

Issues a report on the floorplan macro array set by using the **set_mpc_macro_array** command.

SYNTAX

```
status report_mpc_macro_array
[macro_array]
```

Data Types

macro_array string

ARGUMENTS

macro_array
Reports floorplan macro options for all macro arrays or the macro arrays listed in *macro_array*.

DESCRIPTION

This command reports various options set by the **set_mpc_macro_array** command.

For more information about these floorplan options, read the man page description of the **set_mpc_macro_array** command.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows a sample report.

`set_mpc_macro_options(2)`

report_mpc_macro_options

Issues a report about the floorplan macro options.

SYNTAX

```
int report_mpc_macro_options  
macro_list
```

ARGUMENTS

macro_list

Reports floorplan macro options for the macros listed.

DESCRIPTION

This command reports various options set by the **set_mpc_macro_options** command to constrain macros during the automatic generation of the floorplan, using the minimal physical constraints method.

For more information about these floorplan options, read the man page description of the **set_mpc_macro_options** command.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

report_mpc_options

Issues a report about the floorplan options.

SYNTAX

```
int report_mpc_options
```

ARGUMENTS

The **report_mpc_options** command has no arguments.

DESCRIPTION

This command reports all the floorplan options set for running a minimal physical constraints flow. Use these options to generate a floorplan automatically, using the **set_mpc_options** command. Also, see the **set_mpc_options** command man page to learn the default values of the options and a description of how each option relates to the automatically generated floorplan.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows a report:

```
prompt> report_mpc_options
          Report of floorplan options
          -----

report_mpc_pnet_options

Issues a report about the floorplan pnet options.

SYNTAX

```
int report_mpc_pnet_options  
-name
```

ARGUMENTS

```
-name  
Display the pnet options for pnet options matching name.
```

DESCRIPTION

This command report all the options set using the **set_mpc_pnet_options** command.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows a report:

```
prompt> report_mpc_pnet_options  
report_mpc_pnet_options

```

SEE ALSO

set_mpc_macro_options(2)
set_mpc_options(2)
set_mpc_pnet_options(2)
set_mpc_port_options(2)

report_mpc_port_options

Issues a report about the floorplan port options.

SYNTAX

```
int report_mpc_port_options  
port_list
```

ARGUMENTS

```
port_list  
Reports floorplan port options for the ports listed.
```

DESCRIPTION

This command reports various port options set by the **set_mpc_port_options** command, the man page of which describes the options. Set these options to constrain the ports during a minimal physical constraints method flow. Use the **set_mpc_port_options** command to set different options to constrain the ports during automatic generation of the floorplan.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows a sample report:

```
prompt> report_mpc_port_options  
  
Report of floorplan port options  
-----  
PORT      SIDE    LAYER   ORIENT    X-BOUNDS    Y-BOUNDS

report_mpc_rectilinear_outline

Issues a report about the floorplan rectilinear outline.

SYNTAX

```
int report_mpc_rectilinear_outline
```

ARGUMENTS

The **report_mpc_rectilinear_outline** command has no arguments.

DESCRIPTION

This command reports rectilinear outline set by the **set_mpc_rectilinear_outline** command, the man page of which describes the options. .

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows a sample report:

```
report_mpc_rectilinear_outline
*****
Report mpc core outline
Design : MRISC
Version: W-2004.12
Date   : Fri Sep 24 18:02:05 2004
*****
{0.000 0.000} {1000.000 0.000} {1000.000 1500.000}

report_mpc_ring_options

Issues a report about the mpc ring options.

SYNTAX

```
int report_mpc_ring_options
```

ARGUMENTS

The **report_mpc_ring_options** command has no arguments.

DESCRIPTION

This command reports all the options set by using the **set_mpc_ring_options** command.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows a report:

```
prompt> report_mpc_ring_options
report_mpc_ring_options
*****
Report floorplan Ring options
Design : MRISC
Version: U-2003.06-CTGbeta2_PSYNalpha
Date   : Thu Feb 20 19:16:26 2003

report_mtcmos_pna_strategy

Prints the current values and default values for the parameters controlled by **set_mtcmos_pna_strategy**.

SYNTAX

```
status_value report_mtcmos_pna_strategy
```

ARGUMENTS

The **report_mtcmos_pna_strategy** command has no arguments.

DESCRIPTION

Prints the current values and default values for the parameters controlled by **set_mtcmos_pna_strategy**. These parameters are used to control power network synthesis (PNS) and power network analysis (PNA), when exploring, replacing, optimizing MTCMOS cell size (**optimize_header_footer**, **explore_header_footer** and **replace_header_footer**).

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLE

The following example shows a sample output of the **report_mtcmos_pna_strategy** command.

```
prompt> report_mtcmos_pna_strategy

Power Budget:           default
Voltage Supply:        default
Lowest Voltage Drop:   false
Target Voltage Drop:   default
Pad Lib Cell:          null
Read Pad Cell File:    null
Read Pad Lib Cell File: null
Use Strap Ends As Pads: false
Use Pins As Pads:       false
Create Virtual Rails:   null
Synthesize Voltage Areas: null
Disable Snap To Row&Tile: false
Relative To Voltage Area: false
Pattern for inserting MTCMOS:      normal
1
prompt>
```

SEE ALSO

`synthesize_fp_rail(2)`

report_mw_design_ecos

Report ECO history information and output specific ECO changelist

SYNTAX

```
int report_mw_design_ecos
[design_name]
[-output outfile_name]
[-history]
[-id id_number]
```

Data Types

<i>design_name</i>	string
<i>outfile_name</i>	string
<i>id_number</i>	integer

ARGUMENTS

design_name
The name of Milkyway design cell whose history will be reported

-output outfile_name
The file name to which the command output change list or history information; if not specified, stdout will be used to output.

-history
This option will make the command to report ECO history of all changes, including flat ECO changes and hierarchical ECO changes in the design cell.

-id id_number
This option specifies the ECO Id to be reported; if not specified, the latest ECO change will be reported.
NOTE: The hierarchy preservation data and the flat design data of the cells must be consistent. Both cells will be opened in read-only mode.

DESCRIPTION

This command will report all ECO change history of given design or output specific ECO change list of given id number.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

Following are examples of reporting ECO history information on Milkyway design cells.

The following example is to get latest ECO change list

```
prompt> report_mw_design_ecos
```

The following example is to get latest ECO change list and save to ECO change file

```
prompt> report_mw_design_ecos
          -output eco_changefile
```

The following example is to report all ECO history information

```
prompt> report_mw_design_ecos
          -history
```

The following example is to get specific ECO change list by ECO id of given design cell and save the list to ECO change file

```
prompt> report_mw_design_ecos
          -id 3
          -output eco_changefile_3
```

SEE ALSO

`read_mw_eco_list(2)`

report_mw_lib

Displays information about a Milkyway library.

SYNTAX

```
status_value report_mw_lib
[-unit_range]
[-mw_reference_library]
mw_lib
```

Data Types

mw_lib string

ARGUMENTS

-unit_range
Indicates to list the information of the unit. This option requires the library to be reported on to be specified.

-mw_reference_library
Prints the list of reference libraries for the Milkyway library. If the library is not be specified, the current Milkyway library is used.

mw_lib
Specifies the Milkyway library to be reported. The default is the current Milkyway library.

DESCRIPTION

This command displays information about a Milkyway library.

A status indicating success or failure is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example displays Reference Library information about a Milkyway library design:

```
prompt> report_mw_lib -mw_reference_library design
      ./libs/mw/nand_macro_reflib_018
      1
```

The following example displays unit information about a Milkyway library design:

```
prompt> report_mw_lib -unit_range design
```

Library: design

report_name_rules

Reports the values of name rules.

SYNTAX

```
int report_name_rules  
[name_rules]
```

Data Types

name_rules string

ARGUMENTS

name_rules

Specifies the name of the rules to be reported. If *name_rules* is not specified, all currently defined name rules are reported.

DESCRIPTION

Reports the values of a set of name rules. Name rules are created or modified by **define_name_rules**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **report_name_rules** to report the values of the name rules called "EXAMPLE".

```
prompt> report_name_rules EXAMPLE  
*****  
Report : name_rules  
Name Rules : EXAMPLE  
Version: v3.0  
Date   : Fri Sep 27 11:10:20 1991

SEE ALSO

`change_names(2)`
`define_name_rules(2)`
`report_names(2)`

report_names

Reports potential name changes of ports, cells, and nets in a design.

SYNTAX

```
int report_names
[-rules name_rules]
[-hierarchy]
[-dont_touch designs_list]
[-nosplit]
[-original]
```

Data Types

<i>name_rules</i>	string
<i>designs_list</i>	list

ARGUMENTS

-rules *name_rules*

Specifies a set of name rules to which names must conform. The *name_rules* must be defined with the **define_name_rules** command. By default, the name rules file specified in **default_name_rules** is used.

-hierarchy

Reports all names in the design hierarchy. By default, only objects within the current design are reported.

-dont_touch *designs_list*

Specifies a list of designs to which the **changes_names** command is not applied.

-nosplit

Prevents line splitting when column fields overflow.

-original

Reports original names only, and does not report changes.

DESCRIPTION

The **report_names** command reports names of ports, cells, and nets that would be changed to conform to the specified name rules.

This command may not report all of the name changes that would occur by the **change_names** command.

The **report_names** is normally used before running the **change_names** command. The output of **report_names** can be redirected to a names file and used as input to **change_names**.

The *name_rules* file specifies the rules for modifying names, and must be defined with **define_name_rules**.

Use **report_name_rules** to display a list of name rules currently available. Refer to the **define_name_rules** man page for information about naming rules that can be affected when running **report_names**.

With no options specified, **report_names** operates on ports, cells, and nets in the current design. When **-hierarchy** is specified, the report is expanded to include all design objects within the current design object hierarchy.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports port, cell, and net names in the current design that do not conform to the rules defined in **default_name_rules**:

```
prompt> list default_name_rules
default_name_rules = "EXAMPLE"

prompt> report_names
*****
Report : names
      -rules EXAMPLE
Design : TOP
Version: v3.0
Date   : Tue Aug 13 14:24:23 1991
*****  
  
Design          Type    Object           New Name
-----  
TOP            cell    U$1              U_1  
TOP            net     NET_NAME_IS_WAY_TOO_LONG  
                           NET_NAME_IS_WAY_TOO  
TOP            net     12345             N12345  
  
prompt> change_names -names_file TOP.names
Information: 15 names changed using names file 'TOP.names'.
```

SEE ALSO

change_names(2)
define_name_rules(2)
report_name_rules(2)

report_net

Reports net information for the design of the current instance or for the current design.

SYNTAX

```
status report_net
[-nosplit]
[-noflat]
[-transition_times]
[-only_physical]
[-verbose]
[-cell_degradation]
[-min]
[-connections]
[-physical]
[net_list]
[-significant_digits digits]
[-max_toggle_rate]
[-scenario scenario_list]
```

Data Types

<i>net_list</i>	list
<i>digits</i>	integer
<i>scenario_list</i>	list

ARGUMENTS

-nosplit
Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds its column's width, the next field begins on a new line, starting in the correct column.

-noflat
Allows backward compatibility to produce net reports that only trace fanin and fanout for the current level of hierarchy in a design. The **report_net** command, by default, displays fanin and fanout information throughout the hierarchy for each net, as if the net were flattened. Earlier versions of **report_net** report the fanin and fanout for a net only at the current level of hierarchy.

-transition_times
Reports the rise and fall transition times for each net at the end of the report.

-only_physical
Reports the preroutes of the physical net.

-verbose
 Reports verbose connection information when used with the **-connections** option. When used with the **-physical** or **-only_physical** options, this option displays detailed physical information.

-cell_degradation
 Reports the capacitance on the net, the limit for the capacitance on the net (calculated from the cell_degradation table for the drivers of the net), and violations on the net at the end of the report.

-min
 Reports the minimum value of capacitance, resistance, or transition time instead of the maximum. By default, **report_net** displays only the maximum values.

-connections
 Reports information about pins connected to the nets.

-physical
 Reports the total wire length of the net and preroutes of the net, if preroute information exists.

net_list
 Reports only those nets specified in *net_list*. If you do not specify *net_list*, all nets in the current instance are displayed.

-significant_digits *digits*
 Specifies the number of digits to the right of the decimal point to report. Allowed values are 0 through 13. The default value is 2. Using this option overrides the value set by the **report_default_significant_digits** variable.

-max_toggle_rate
 Shows the maximum toggle rate values for each net.

-scenario *scenario_list*
 Reports the timing derate for the specified list of scenarios in a multi-scenario design. Inactive scenarios are skipped in the report. Each scenario is reported separately. If this option is not specified, only the current scenario is reported.

DESCRIPTION

The **report_net** command displays information about the nets in the design of the current instance or in the current design. If **current_instance** is set, the report is generated for the design of that instance. Otherwise, the report is generated for the current design.

The Load column is calculated as Load = Cell_input_cap + Wireload_cap. Attributes such as **dont_touch** and **annotated_capacitance** are displayed for each net. Note that **dont_touch** can be present on a net as an implicit attribute. This may occur when the **set_dont_touch_network** command is used. All of the nets in the transitive fanout of a port are affected, but **dont_touch** cannot be removed independently from these nets. The annotated capacitance is the value set by the **set_load** command on a net.

If you specify the **-connections** option, the leaf cell pins connected to each net are listed.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenario** option.

EXAMPLES

The following is an example of a net report:

```
prompt> report_net

*****
Report : net
Design : CONTROL
Version: v3.1a
Date   : Fri 1993
*****

Operating Conditions: WCCOM

```
report_default_significant_digits(3)
```

report_net_changes

Reports net changes that occurred during some IC Compiler optimizations, such as `place_opt`, `create_buffer_tree`, and `route_opt`.

SYNTAX

```
int report_net_changes
[-verbose]
```

DESCRIPTION

The IC Compiler **report_net_changes** command provides a methodology for the user to identify net changes between the post-synthesis netlist (PSL) and the post-layout netlist (PLN) for the purpose of performing ECO changes and other tasks.

The PSL is usually the output of Design Compiler and input to IC Compiler. The PLN is the final or an intermediate result of IC Compiler.

The environment variable **icc_track_net_changes** is FALSE by default. When the user sets it true, net names will be preserved during IC Compiler optimization processes as much as possible: `clock_opt`, `route_opt`, `place_opt`, `balance_inter_clock_delay`, `create_buffer_tree`, etc. Net name creations during these optimizations will be "tracked" so that the user can report the created nets later. Deleted nets will not be tracked or reported.

Nets derived by optimization processes (such as buffering) will be given names with the same prefix as the original net. Nets touching hierarchical boundaries will not be renamed, as they must match the boundary name while exporting the design.

report_net_changes will report on the "tracked" net name changes to help the user find the collections of nets that are derived from an original net. Nets that are reported together are logically equivalent to the original net.

LIMITATIONS

Setting **icc_track_net_changes** TRUE does not ensure that net names in the IC Compiler result are necessarily equivalent to the nets in the original PSL (input to IC Compiler), because various commands and flows can change the names and functions of nets in ways that cannot be tracked.

Examples of changes that cannot be tracked are:

-- Netlist editing and other commands, such as **change_names**: these commands may seriously disrupt the name correspondence between nets in the post-synthesis netlist and nets in the post-layout netlist. After re-connecting nets with **disconnect_net** and **connect_net**, the net names may have different logical functions: thus net name equivalence does not (in general) imply functional equivalence between the PSN and the PLN.

-- 3rd-party flows with unknown transformations and name changes are not tracked. The **icc_track_net_changes** methodology does not ensure that net names have the same function over time. If a netlist is imported to IC Compiler from a 3rd party tool,

it is a new starting point and net name tracking begins from that point. There is no way currently to re-introduce net tracking information if the design is exported to a 3rd-party tool and then re-imported to IC Compiler. Verilog files do not contain any tracking information. No name tracking will be present immediately after reading a Verilog file into ICC. If the user outputs Verilog and then rereads the Verilog file, the net name tracking will be lost.

-- There is currently no command to re-compute or verify functional correspondence based on net names.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

report_net_changes reports on the nets that are derived from one original net. The report only mentions nets that have been changed. Nets with no changes are not mentioned. Some comments (after <==) are included to explain the behavior during this example where the only changes to the netlist are due to a hierarchical net being buffered.

```
prompt> create_buffer_tree TGT_RESETJ
1
prompt> report_net_changes

Original net:  TGT_RESETJ           <== High fanout synthesis net
Changed to:
  TGT_RESETJ
  TGT_RESETJ_1                  <== Maintains prefix of root net
  TGT_RESETJ_2  (inverted)      <== Indicates inversion of original net.
  ASYNC/TGTRLEN/RESETJ
  ASYNC/TGT_RESETJ_hfs_netlink_8
  ASYNC/S2T/RESETJ              <== Original hierarchical port net reuses name
  ASYNC/S2T/RESETJ_hfs_netlink_38 <== New hierarchical port net unique
  ASYNC/S2T/RESETJ_hfs_netlink_39
1
```

SEE ALSO

`change_names(2)`

report_net_fanout

Displays net fanout or buffer tree information for the current design.

SYNTAX

```
status report_net_fanout
[-nosplit]
[-high_fanout]
[-threshold lower]
[-bound upper]
[-verbose]
[-connections]
[-physical]
[-min]
[-tree [-depth level]]

<i>upper</i>	integer
<i>level</i>	integer
<i>net_list</i>	list

ARGUMENTS

-nosplit

Prevents line-splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds its column's width, the next field begins on a new line in the same column.

-high_fanout

Specifies to show high fanout nets only. A high fanout net is a net with more fanouts than **500**. A high fanout buffer tree is a buffer tree with more leaf loads than the specified value. The fanouts cross hierarchies.

This option is mutually exclusive with the **-threshold** option.

-threshold *lower*

Specifies to only show nets with more fanout than *lower*. The fanouts cross hierarchies.

This option is mutually exclusive with the **-high_fanout** option.

-bound *upper*

Specifies to only show nets with fanout less than or equal to *upper*. The fanouts cross hierarchies.

-verbose

Displays verbose information.

-connections

Displays information about pins connected to the nets.

```

-physical
    Displays location information when applicable.

-min
    Shows the minimum conditions. By default, only maximum conditions are shown.

-tree
    Indicates to treat a buffer tree as transparent. The leaf loads of the buffer
    tree are treated as the fanouts of the net. Hierarchical boundaries are not
    considered as leaf loads.
    This option is mutually exclusive with the net_list argument.

-depth level
    Indicates to only display buffer trees with more levels than level. This
    option can only be used with the -tree option.

net_list
    Specifies to process only those nets on the net_list. If net_list is not
    specified, all nets in the current instance are processed.
    This argument is mutually exclusive with the -tree option.

```

DESCRIPTION

The **report_net_fanout** command displays net fanout or buffer tree information in the current design. If a *net_list* is specified, the report is generated only for the specified nets.

All reports cross hierarchical boundaries as if the nets were flattened. This is consistent with the **report_net** command.

The **report_net_fanout** command can be used to find high fanout nets, buffer trees, or long buffer chains in the current design or the current instance.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to find high fanout nets:

```
prompt> report_net_fanout -high_fanout
```

The following example shows how to find high fanout nets in a particular set of nets:

```
prompt> report_net_fanout -high_fanout [get_nets scan*]
```

The following example shows buffer trees with 10 leaf pins:

```
prompt> report_net_fanout -tree -threshold 9 -bound 10
```

The following example shows how to find long buffer chains.

```
prompt> report_net_fanout -tree -depth 8 -bound 1
```

SEE ALSO

```
create_buffer_tree(2)
current_design(2)
current_instance(2)
remove_buffer_tree(2)
report_buffer_tree(2)
```

report_net_routing_layer_constraints

Reports routing layer constraints for specific nets.

SYNTAX

```
int report_net_routing_layer_constraints  
list_of_nets
```

Data Types

list_of_nets list

ARGUMENTS

list_of_nets
Lists the net names for which to report routing layer constraints.

DESCRIPTION

This command reports routing layer constraints for specific nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the routing layer constraints for a net named netA.

```
prompt> report_net_routing_layer_constraints {netA}
```

SEE ALSO

```
remove_net_routing_layer_constraints(2)  
set_net_routing_layer_constraints(2)
```

report_net_routing_rules

Displays a report of user-specified routing rules for the specified nets.

SYNTAX

```
int report_net_routing_rules
list_of_nets
```

Data Types

list_of_nets list

ARGUMENTS

list_of_nets
Lists the net names for which to report nondefault rules.

DESCRIPTION

This command lists all nondefault routing rules for the specified nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports nondefault routing rules for nets named CLK1 and CLK2.

```
prompt> report_net_routing_rules {CLK1 CLK2}
----- Nets with non-default routing rules -----
CLK1 : SP1
CLK2 : SP1

----- All other nets use DEFAULT routing rule -----
-----
```

The following example reports nondefault routing rules for nets named CLK3 and CLK4.

```
prompt> report_net_routing_rules {CLK3 CLK4}
----- All nets use DEFAULT routing rule -----
-----
```

The following example reports nondefault routing rules for all nets.

```
prompt> report_net_routing_rules [get_nets -hier]
----- Nets with non-default routing rules -----
CLK1 : SP1
CLK2 : SP1
```

----- All other nets use DEFAULT routing rule -----

SEE ALSO

`set_net_routing_rule(2)`

report_noise

Reports static noise for the worst pins or the specified pins, or all violators.

SYNTAX

```
status report_noise
[-nworst_pins worst_pin_count]
[names]
[-slack_lesser_than slack_limit]
[-all_violators]
[-verbose]
[-significant_digits digits]
[-slack_type area | height]
```

Data Types

<i>worst_pin_count</i>	int
<i>names</i>	string
<i>slack_limit</i>	float
<i>digits</i>	int

ARGUMENTS

-nworst_pins *worst_pin_count*

Specifies the number of load pins to be reported. Any number greater than 1 is accepted; the default value is 1.

names

Lists pin names. By default, this option is off.

-slack_lesser_than *slack_limit*

Indicates that only those pins with a slack less (more negative) than *slack_limit* are to be shown.

-all_violators

Indicates that only violating pins (negative slack) are to be shown. This option cannot be used with the **-slack_lesser_than** option. If this option is used with the **-nworst_pins** option, the number of violating pins will be limited by that value.

-verbose

Shows more details about the calculation of total noise on each load pin, including the individual contribution of each aggressor .

-significant_digits *digits*

Specifies the number of digits after the decimal point to be displayed for time values in the generated report, default value is 2.

-slack_type area | height

Specifies the type of slack to be used. Valid values are area, height. A *slack_type* of area reports slack as the voltage margin multiplied by the noise bump width. The voltage margin is defined by the noise bump height and noise

immunity curves. This setting is the default. A *slack_type* of height reports noise slack as the voltage margin.

DESCRIPTION

This command reports static noise (width, height, and slack) for the worst pins or the specified list of pins. It computes "between rail noise," which is above low and below high noise. It uses slack type height or area.

To properly use the **report_noise** command in ICC, you must enable static noise by setting The **set_si_options** command option **-static_noise** to **true**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example reports the static noise values for the **5** worst pins.

```
prompt> report_noise -nworst_pins 5
*****

SEE ALSO

`set_si_options(2)`
`report_noise_calculation(2)`

report_noise_calculation

Displays the actual calculation of noise information for the specified net arc.

SYNTAX

```
status report_noise_calculation
[-significant_digits digits]
-from from_pin
-to to_pin
```

Data Types

digits int

ARGUMENTS

-significant_digits *digits*

Specifies the number of digits after the decimal point to be displayed for the values in the generated report, default value is 2. This option controls only the number of digits displayed, not the precision used internally for analysis.

-from *from_pin* **-to** *to_pin*

Specifies the start and end points of a net arc within a design. The *from_pin* must be a driver pin or port, and the *to_pin* must be the load pin or port of the same net.

DESCRIPTION

Displays details of the noise calculation for the specified net arc. The report shows some general information about the victim, as well as details of noise bump and noise slack calculations.

The noise calculation section includes the noise bumps induced from each of the aggressors. The aggressor attribute column shows more details about each of the effective aggressors. Aggressors which are filtered are not included in this report. The following is the list of possible attributes an aggressor can have:

Attributes: A - aggressor is active S - aggressor is screened

Active aggressor is an aggressor which contributes to the worst case alignment scenario of all the aggressors.

Aggressor can be screened from the analysis if it has no significant impact on the victim.

The noise slack calculation section shows the details of how the area slack and height slack is derived for the victim, and also what kind of constraint was used to derive the slack. The height slack is the difference of the actual bump height versus the bump height which causes the failure with the same width. The area slack is the area that needs to be added to the actual bump to cause a noise failure.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example specifies a noise calculation report for the driver pin exetop0/e_dptop0/e_flag0/I27/Y and load pin exetop0/e_dptop0/e_flag0/U1/A :

```
*****
Report : noise calculation
        -from exetop0/e_dptop0/e_flag0/I27/Y

report_operating_conditions

Display a specific or all the operating conditions in a library.

SYNTAX

```
int report_operating_conditions  
-library library_name  
[-name op_cond_name]
```

Data Types

<i>library_name</i>	string
<i>op_cond_name</i>	string

ARGUMENTS

-library <i>library_name</i>	Specifies the name of the library that stores the operating conditions.
-name <i>op_cond_name</i>	Specifies the name of the operating conditions.

DESCRIPTION

The **report_operating_conditions** command reports a specific or all the operating conditions in the specified library.

To create a new operating conditions, use **create_operating_conditions**.

To set operating conditions on the current design, use **set_operating_conditions**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports a specific operating conditions called "BEST" in the library "a_lib".

```
prompt> report_operating_conditions -library a_lib -name BEST
```

The following example reports all the operating conditions in the library "IBM_CMOS5S6_SC".

```
prompt> report_operating_conditions -library IBM_CMOS5S6_SC
```

SEE ALSO

`create_operating_conditions(2)`
`set_operating_conditions(2)`

report_optimize_dft_options

Reports options for physical design-for-test (DFT) optimization.

SYNTAX

```
status report_optimize_dft_options
```

ARGUMENTS

The **report_optimize_dft_options** command has no argument.

DESCRIPTION

This command reports the value of the physical DFT options available in command 'set_optimize_dft_options'. The options are '-repartitioning_method' and '-single_dir_option'.

SEE ALSO

`optimize_dft(2)`
`set_optimize_dft_options(2)`

report_optimize_pre_cts_power_options

Reports the option settings for **optimize_pre_cts_power** command.

SYNTAX

```
status_value report_optimize_pre_cts_power_options
```

ARGUMENTS

The **report_optimize_pre_cts_power_options** command has no arguments.

DESCRIPTION

This command reports all the option values for the **optimize_pre_cts_power** command. The main options to enable pre-CTS power optimizations are **-low_power_placement** and **-clock_gating** in **set_power_options** command. All other options are set by the **set_optimize_pre_cts_power_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the current options to be used by the **optimize_pre_cts_power**.

```
prompt> report_optimize_pre_cts_power_options
```

SEE ALSO

```
optimize_pre_cts_power(2)
set_optimize_pre_cts_power_options(2)
set_power_options(2)
```

report_parameter

Reports the details of a parameter, such as name, type, current value, default value, valid range, and a brief description.

SYNTAX

```
int report_parameter
[-name name]
[-module route | groute | droute | trackAssign | ek | preroute | sr | all]
[-type integer | real | string]
```

Data Types

name string

ARGUMENTS

-name *name*

Specifies the name of the parameter to be reported.

-module route | groute | droute | trackAssign | ek | preroute | sr | all

| ek | preroute | sr | all

Specifies the module for which to report parameters. The valid module names are as follows:

route
groute
droute
trackAssign
ek
preroute
sr
all

By default, or if you use this option with the **all** argument, the tool reports the parameters for all of the parameters in all of the modules supported by the **report_parameter** command.

-type integer | real | string

Specifies the parameter type.

DESCRIPTION

This command reports the details of a parameter, such as name, type, current value, default value, valid range, and a brief description. If you do not specify any arguments, it reports all of the parameters in all of the supported modules.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the details of the *timingdriven* parameter:

```
prompt> report_parameter -name timingdriven
```

The following example reports the details of parameters in the **groute** module:

```
prompt> report_parameter -module groute
```

The following example reports the details on all of the parameters in all of the modules supported by the **report_parameters** command:

```
prompt> report_parameter
```

SEE ALSO

`set_parameter(2)`

report_path_group

Reports information about path groups in the current design.

SYNTAX

```
status report_path_group
[-nosplit]
[-expanded]
[-scenario scenario_list]
```

ARGUMENTS

-nosplit
Prevents line splitting and facilitates writing software to extract information from the report output. Most design information is listed in fixed-width columns. When the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-expanded
Expands the paths when reporting.

-scenario *scenario_list*
Reports path groups for given list of scenarios of a multiscenario design. Inactive scenarios will be skipped in the report. Each scenario is reported separately. If this option is not given, only the current scenario is reported.

DESCRIPTION

The **report_path_group** command produces a report showing information about path groups in the current design. The report includes path groups automatically created by the **create_clock** command and groups manually created with the **group_path** command. Path groups are used to affect the calculation of maximum delay cost during optimization. You can display the cost of each group using the **report_constraint** command.

To remove all path groups in the current design, use the **reset_design** command. To remove certain paths from their current groups, use **group_path -default**.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenario** option.

EXAMPLES

The following example reports all timing attributes set on the design:

```
prompt> report_path_group
```

```
*****
Report : path_group
Design : counter
Version: 1998.01
Date   : Wed Jul  9 13:51:14 1997
*****
```

Group Name	Weight	Range	
default	1.00	0.00	
CLK	1.00	0.00	
BLUE	1.00	5.00	

Paths:

report_pg_net

Reports power and ground net information for the opened Milkyway design.

SYNTAX

```
status report_pg_net
[-net net_list]
[-connections]
```

Data Types

net_list list

ARGUMENTS

-net *net_list*

Reports only those nets specified in **-net** option. If you do not specify **-net** option, all power and ground nets are reported.

-connections

Reports information about pins connected to the power and ground nets. By default, this option is set as false.

DESCRIPTION

The **report_pg_net** command displays information about the power and ground nets of the current opened Milkyway design. By default, will report all the power and ground nets in all hierarchical level of the design. Option "**-net**" can be used to report only specified power and ground nets. "**-net**" option can take a collection of power and ground nets, the collection can be generated by **get_nets** command with "**-all**" option for power and ground net selection.

For each net, will report net name, net type which can be either "power" or "ground", UPF power domain name of the net if available, number of pins and port which connected to the net, and the detail list of connected pins and port if option "**-connections**" specified.

if option "**-connections**" is specified, will report all pins and port which connected to the net.

.SH EXAMPLES The following is an example of report_pg_net output:

```
prompt> report_pg_net -net [get_nets -physical {VDD*}]
```

```
***** Report: pg net Options: -net Design: top

```
.SH "SEE ALSO" get_nets(2)
```

report_physical_bus

Displays information about physical bus.

SYNTAX

```
status report_physical_bus
[physical_bus_list]
```

Data Types

physical_bus_list list

ARGUMENTS

physical_bus_list

Specifies the list of physical buses to be reported.

You can specify element of the list with a name pattern of physical buses or a collection containing physical buses.

By default, all physical buses in the current design are reported.

DESCRIPTION

This command displays information about the specified physical buses.

In the report, nets in a physical bus are listed following the order in that physical bus.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a new physical bus then reports it with the command **report_physical_bus**.

```
prompt> create_physical_bus -sort ascending -nets [get_nets UPC_DATA*] bus1
{bus1}
prompt> report_physical_bus bus1
*****
Report : physical_bus

report_physical_signoff_options

Reports option values set by set_physical_signoff_options that are shared (in common) by signoff_drc command and signoff_metal_fill command, etc.

SYNTAX

```
status report_physical_signoff_options
[-default]
```

ARGUMENTS

```
-default
Report default options of set_physical_signoff_options.
```

DESCRIPTION

This command reports option values that have been set by set_physical_signoff_options command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **report_physical_signoff_options** command.

```
prompt> set_physical_signoff_options \
-exec_cmd icv \
-dp_hosts {machine_1 machine_2 machine_3 machine_4} \
-num_cpus 4 \
-drc_runset drc.rs \
-fill_runset fill.rs \
-mapfile layermap
```

```
prompt> report_physical_signoff_options
```

```

report_pin_guides

SYNTAX

```
status report_pin_guides
[{-pins pins_collection
  | -nets nets_collection}]
[pin_guides]
```

Data Types

<i>pins_collection</i>	collection
<i>nets_collection</i>	collection
<i>pin_guides</i>	collection

ARGUMENTS

```
-pins pins_collection
      Reports pin guides associated with the pins specified by the pins_collection argument.

-nets nets_collection
      Reports pin guides associated with the nets specified by the nets_collection argument.

pin_guides
      Specifies a collection of pin guides.
```

DESCRIPTION

This command reports details of the specified pin guides, the pin guides attached to the specified pins, the pin guides attached to the specified nets, or all pin guides (if no options are specified).

Each plan group pin guide is output in the following format:

```
Pin Guide: name
BBox: {{xmin ymin} {xmax ymax}}
PlanGroup: {parent_name}
Nets: {child_name ...}
```

Each soft macro pin guide is output in the following format:

```
Pin Guide: name
BBox: {{xmin ymin} {xmax ymax}}
SoftMacro: {parent_name}
Pins: {child_name ...}
```

where:

```
name -
  Pin Guide Name
```

```
 {{xmin ymin} {xmax ymax}} -  
     Bounding Box of the Pin Guide  
 {parent_name} -  
     Parent Plan Group or Soft Macro name  
 {child_name ...} -  
     List of the names of the pins or nets attached to the pin guide
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports all pin guides attached to the pins A, B or C.

```
prompt> report_pin_guides -pins [get_pins {A B C}]
```

SEE ALSO

```
create_pin_guide(2)  
get_pin_guides(2)
```

report_pin_name_synonym

Reports pin name synonym definitions.

SYNTAX

```
status report_pin_name_synonym  
[-nosplit]
```

ARGUMENTS

-nosplit

Prevents line splitting. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_pin_name_synonym** command displays all of the currently defined pin name synonyms.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLE

The following command set shows the pin name synonym settings and then uses the **report_pin_name_synonym** command to report pin name synonyms:

```
prompt> set_pin_name_synonym SYN_CD CD
1
prompt> set_pin_name_synonym SYN_QN QN
1
prompt> set_pin_name_synonym -full_name \
           mid1/bot1/LSR0P_at_bot/SYN_R mid1/bot1/LSR0P_at_bot/R
1
prompt> set_pin_name_synonym -full_name this/is/a/synonym mid1/FJK2SP_at_mid/TI
1
prompt> set_pin_name_synonym -full_name mid1/FJK2SP_at_mid/J mid2/bot2/LSR0P_at_bot/
Q
1
prompt> report_pin_name_synonym

*****
Report : pin name synonym
Design : top
Version: X-2005.09
Date   : Wed Jun 29 10:29:04 2005
*****
```

Synonym	Pin Name	Type

this/is/a/synonym	mid1/FJK2SP_at_mid/	
TI full name		
mid1/FJK2SP_at_mid/J	mid2/bot2/LSR0P_at_bot/

```

SEE ALSO

`remove_pin_name_synonym(2)`
`set_pin_name_synonym(2)`

report_pin_shape

Displays information about a list of pin shapes.

SYNTAX

```
status report_pin_shape
pin_shape_list
```

Data Types

pin_shape_list list

ARGUMENTS

pin_shape_list
Specifies the list of pin shapes that are to be reported.
You can specify an element of the list with a name pattern of pin shapes or
a collection containing pin shapes.

DESCRIPTION

This command displays information about the specified pin shapes.

EXAMPLES

The following example reports a pin shape tc4/sram_Q[4] using the **report_pin_shape** command.

```
prompt> report_pin_shape tc4/sram_Q[4]
*****
Report : pin_shape
Design : CORE
Version: C-2009.06-ICC
Date   : Sun Dec  6 07:20:27 2008
*****

-----
tc4/sram_Q[4]    M6       Fixed      {{560.000 1707.000} {626.000 1773.000}}
-----
1
```

SEE ALSO

`get_pin_shapes(2)`
`pin_shape_attributes(3)`

report_placement_utilization

Reports the placement utilization for the entire design or a certain region.

SYNTAX

```
status report_placement_utilization
[-non_fixed_only ]
[-grid_size Float]
[-verbose ]
[-coordinates {X1 Y1 X2 Y2}]
```

ARGUMENTS

-non_fixed_only Boolean

Specifies that the utilization reporting will be for "non_fixed standard cell" only. By default, the placement utilization number will be reported for "non_fixed + fixed standard cells". If this option has been specified, the utilization number will be for "non_fixed standard cell only".

The two formulas for calculating the "non_fixed + fixed standard cell" utilization and "non_fixed standard cell only" utilization are different:

a) "non_fixed + fixed" standard cell utilization: The formula is: (Non-Fixed_Std_Cell_Area + Fixed_Std_Cell_Area) / (Total_Area - All_Blockage_Area)

Here "Total_Area" is the area of the entire chip or a certain region if option "-coordinate" has been specified. "All Blockage Area" includes "placement blockage", "hard macros" and "complete pnet blockage".

b) "non-Fixed only" standard cell utilization:

The formula is:

(Non-Fixed_Std_Cell_Area) / (Total_Area - All_Blockage_Area - Fixed_Std_Cell_Area)

-grid_size *Float*

Specifies the grid size of each "sub-region". Besides the entire chip or a user specified region, this command will also divide the given area (either entire chip or a user specified region if option "-coordinate" has been specified) into a set of "sub-regions" and report the corresponding utilization of the "sub-region". So users may have better understanding for the "evenness" of the cell distribution. The "grid_size" will be the size of each "sub-region". By default, the grid size is 5x placement site heights. The Minimum "grid_size" will be 3x placement site heights. The unit for "grid_size" is in micron.

-verbose boolean

Specifies that the utilization number of each "sub-region" will be reported. By default, only the statistic summary of the "sub-region" utilization will be reported.

DESCRIPTION

The **report_placement_utilization** command reports the utilization number for the entire design or a certain region if option "-coordinate" has been specified.

Besides the utilization number, this command will also report the corresponding "total area", "blockage area", "hard macro area", etc. These types of information will be also useful for the users.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **report_placement_utilization** command for the entire chip.

```
prompt> report_placement_utilization
```

The following example runs the **report_placement_utilization** command for a user-specified region.

```
prompt> report_placement_utilization -coordinate {20 20 130 130}
```

SEE ALSO

```
legalize_placement(2)  
check_legality(2)  
report_design(2)
```

report_pnet_options

Issues a report of the options set with the **set_pnet_options** command.

SYNTAX

```
int report_pnet_options
```

ARGUMENTS

There are no arguments to this command.

DESCRIPTION

The **report_pnet_options** command issues a report about the options set on the metal layers using the **set_pnet_options** command. The report is written out in table format. The table columns correspond to the different options used with the **set_pnet_options** command. If the Astro legality checker is enabled, then the route types that are considered are reported below the table. If the Astro legality checker is disabled, then the route types that are considered are reported below the table.

For further information, refer to the **set_pnet_options** command man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows a report of the options in table format:

```
prompt> report_pnet_options
```

`remove_pnet_options(2)`
`set_pnet_options(2)`

report_port

Displays information about ports of the current instance or the current design.

SYNTAX

```
integer report_port
[-drive]
[-verbose]
[-physical]
[-only_physical]
[-nosplit]
[-significant_digits digits]
[port_list]
```

Data Types

<i>digits</i>	integer
<i>port_list</i>	list

ARGUMENTS

-drive

Specifies that the port report is to include only the sections showing the drive capability of input and inout ports. By default, this option is off.

-verbose

Specifies that the port report is to include all port information. By default, only a summary section is shown that lists all ports and their direction.

-physical

Reports the physical location of the port. By default, this option is off.

-only_physical

Reports the physical only ports. By default, this option is off.

-nosplit

Prevents line-splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column. By default, this option is off.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that the command reports. Using this option overrides the value set by the **report_default_significant_digits** variable. Allowed values are **0** through **13**. The default is **2** for all fields except "Pin Load" and "Wire Load," which have a default of **4**. Specifying a valid value for significant digits overwrites the existing default value.

port_list

Indicates that the port report is to include only the specified ports and

cannot be used if the current instance is set. By default, all ports in the current instance or current design are listed.

DESCRIPTION

This command displays information about ports in the design of the current instance or the current design. If the current instance has been set, the report is generated for the design of that instance. Otherwise the report is generated for the current design.

By default, a brief report is produced that includes all ports in the design. If you use the **-verbose** option, all types of information are included. If you use the **-drive** option, only drive information for input and inout ports is shown. If you specify a *port_list* value, the command includes only those ports in the report.

Attributes pertaining to the **set_driving_cell** command that assigned the driving cells to the ports are reported in the "Attrs" column of the driving cell section of the verbose report. The letter **D** indicates that the **-dont_scale** option of the **set_driving_cell** command was used, and the letter **N** indicates that the **-no_design_rule** option was used.

If the current instance has been set, the report is generated for the design of that instance. Note that attributes on these ports have no effect unless the current design is changed to that subdesign.

The "Input Delay" and "Output Delay" portions of the report list the minimum rise, minimum fall, maximum rise, and maximum fall delays. They also list the clock to which the delay is relative. If the clock name is followed by (f), the delay is relative to the falling edge of the clock. Otherwise the delay is relative to the rising edge. If the clock name is followed by (l), input delay is considered as if coming from a level-sensitive latch or output delay is considered as if going to a level-sensitive latch. By default, the delay is relative to a rising edge-triggered device.

The "Max Tran" and "Min Tran" columns list the maximum and minimum rise and fall times set by the **set_transition** command to this port.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows a brief port report:

```
prompt> report_port
```

```

report_port_protection_diodes

Reports the port protection diodes in the current design.

SYNTAX

```
status report_port_protection_diodes
```

ARGUMENTS

This command has no arguments.

DESCRIPTION

The **report_port_protection_diodes** command reports the port protection diodes in the current design.

The reporting format is shown as below:

```
***** Report : port protection diodes Design :  
top Version: A-2007.12-SP2 Date : Fri Jan 25 17:58:35 2008  
*****
```

Name_of_diode_cell diode_location name_of_connected_port

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **report_port_protection_diodes** command.

```
prompt> report_port_protection_diodes
```

SEE ALSO

[insert_port_protection_diodes\(2\)](#)

report_power

Calculates and reports dynamic and static power for a design or instance.

SYNTAX

```
int report_power
[-net]
[-cell]
[-only cell_or_net_list]
[-hier]
[-hier_level level_value]
[-verbose]
[-cumulative]
[-flat]
[-exclude_boundary_nets]
[-include_input_nets]
[-analysis_effort low | medium | high]
[-nworst number]
[-sort_mode mode]
[-histogram [-exclude_leq le_val
    | -exclude_geq ge_val]]
[-nosplit]
[-scenario scenario_list]
```

Data Types

<i>cell_or_net_list</i>	object_list
<i>level_value</i>	integer
<i>number</i>	integer
<i>mode</i>	string
<i>le_val</i>	float
<i>ge_val</i>	float
<i>scenario_list</i>	list

ARGUMENTS

-net

Reports the power consumption of nets. Use the **-net** option alone, or use it with the **-cell** option. By default, only the design's summary power information is reported when neither option is specified.

-cell

Reports the power consumption of cells. When using the **-cell** option, some entries in the power report might not apply to certain cells. The column entry for those cells is annotated with N/A. Use the **-cell** option alone or with the **-net** option to report on cells and nets. By default, only the design's summary power information is reported when neither option is specified.

-only *cell_or_net_list*

Specifies a list of cells and/or nets to display with **-net** or **-cell**. With this option, only the cells and/or nets in the *cell_or_net_list* are listed in the power report. If both **-net** and **-only** are specified, the

`cell_or_net_list` must contain at least one net. Similarly, if both **-cell** and **-only** are specified, then the `cell_or_net_list` must contain at least one cell. If the **-net**, **-cell**, and **-only** options are specified together, the `cell_or_net_list` must contain at least one net and one cell.

`-hier`

Specifies that the report be in a hierarchical format, with power information on a block-by-block basis. Use the **-hier_level** option to limit the number of levels of hierarchy shown in the report. The **-sort**, **-cumulative**, **-nworst** options are ignored for this report. The switching, internal, and leakage power numbers are reported for each hierarchical block. The hierarchy is shown through indentations.

In DC-Topographical mode, with **-hier** option the power report includes estimated clock tree power numbers if power prediction was turned on in the last **compile_ultra** run. This entry is marked *CLOCK_TREE_EST*.

`-hier_level level_value`

Specifies the number of levels of hierarchy to display in the hierarchical report. This option can have any positive integral value greater than 1. Hierarchy levels deeper than the ones specified in this option are not shown in the hierarchical report. This option only modifies the hierarchical report and is ignored for all other types of reports.

`-verbose`

Displays additional detailed information about the power of the cells and/or nets. This option is valid only if **-net** and/or **-cell** is specified.

`-cumulative`

Reports the cumulative dynamic power of the design cells and/or nets. The fanin cumulative power of a cell or net is the dynamic power of the transitive fanin of the start point. Similarly, the fanout cumulative power is the dynamic power of the transitive fanout of the start point. The transitive fanin and fanout include and stop at sequential cells and primary design ports. The cumulative dynamic power includes the switching activity of all nets, and the internal power of all cells in the fanin or fanout. For every cell in the transitive fanin and fanout, both the cell's internal power and the switching power of the nets driven by the cell are included. The fanout cumulative power of a net includes the net's switching power but not the internal power of the cell(s) driving the net. The cumulative report is displayed after the standard cell or net report. The **-cumulative** option is only valid if the **-net** or **-cell** flag is specified.

`-flat`

Specifies that the power report traverse the hierarchy and report objects at all lower-levels (as if the design's hierarchy were flat). The default is to report objects at only the current level of hierarchy. For cell reports, if **-flat** is not specified, the power reported for a subdesign is the total power estimate for that subdesign, including all of its contents.

`-exclude_boundary_nets`

Specifies an option that is now obsolete.

`-include_input_nets`

Includes the switching power of primary input nets in the power report. The default is to exclude boundary input nets. This option affects the nets that

are chosen to be displayed in the net-specific report as well as the value of the total switching power. This option does not affect the cell leakage and internal power values.

-analysis_effort low | medium | high

Provides a tradeoff between runtime and accuracy. The default value is **low**. Specifying **low** effort results in the fastest runtime and the lowest accuracy of power estimates. Specifying **medium** or **high** effort results in a longer run that has increasing levels of accuracy. The analysis effort is considered only during the estimation of switching activity information, and, therefore, has an effect only when the design is not fully annotated with switching activity.

-nworst *number*

Filters the report so that it displays only the highest *number* power objects. This option is valid only if either **-net** and/or **-cell** is specified.

-sort_mode *mode*

Determines the sorting mode for report order and **-nworst** selection. The valid sorting modes for the **-net** or **-cell** options are as follows:

-net option	-cell option
-----	-----
name	name
cumulative_fanout	cumulative_fanout
cumulative_fanin	cumulative_fanin
net_static_probability	cell_internal_power
net_switching_power	cell_leakage_power
net_toggle_rate	dynamic_power
total_net_load	

When using both **-net** and **-cell** and specifying a sorting mode, you must select a sorting mode that is valid for both options. The mode is used for both the cell and the net reports.

If you do not explicitly set the sorting mode, a default is chosen based on the mode of the **report_power** command:

Mode	Implicit default
-----	-----
-net	net_switching_power
-cell	cell_internal_power
-net -cell	dynamic_power

-histogram [-exclude_leq *le_val* | -exclude_geq *ge_val*]

Displays a histogram-style report showing the number of nets in each power range. The **-exclude_leq** and **-exclude_geq** arguments are used to exclude data values less than *le_val* or greater than *ge_val*, respectively. Useful for displaying the range and variation of power in the design. This option displays the histogram report only if either **-net** or **-cell** is specified.

-nosplit

Prevents line-splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds its column's width, the next field begins on a new line, starting in the correct column.

```
-scenario scenario_list
    Reports power for given list of scenarios of a multiscenario design. Inactive
    scenarios will be skipped in the report. Each scenario is reported
    separately. If this option is not given, only the current scenario is
    reported.
```

DESCRIPTION

The **report_power** command calculates and reports power for a design. The command uses the user-annotated switching activity to calculate the net switching power, cell internal power, and cell leakage power, and displays the calculated values in a power report. The **report_power** command needs switching activity information on all design nets, and uses a switching activity propagation mechanism to estimate switching activity information on non-annotated design objects.

The options enable you to specify cells and/or nets for reporting. The default operation is to display the summary power values for only the current design. If a current instance is specified, **report_power** displays the summary power values for that instance. The instance's power is estimated in the context of the higher-level design, which means using the switching activity and load of the higher-level design.

The **-verbose** power information. The **-flat**, **-exclude_boundary_nets**, **-nworst**, and **-sort_mode** options enable the filtering of objects that are selected by **report_power**. The **-sort_mode** option also affects the formatting of the power reports by modifying the order of nets and/or cells that are displayed by **report_power**.

The **-cumulative** and **-histogram** options cause additional sections to be displayed in the power reports. The cumulative power section contains transitive fanin and fanout values for cells and/or nets in the design. The power histogram classifies the nets or cells into groups of power values, allowing for easier visual analysis of the range of power values and of the distribution of the nets/cells across that range. The **-histogram** options enable pruning of objects in the histogram by excluding values greater than or less than specified values.

Power analysis uses the current tool's mechanism to obtain loads. For instance, wire load models are used for the case of non-back-annotated non-topographical synthesis, back-annotated capacitances are used when these are available, etc.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows a **report_power** summary report. A medium effort analysis is performed to estimate the design's power values.

```
prompt> report_power -analysis medium
```

```
Information: Updating design information... (UID-85)
Performing probabilistic propagation through design.
```

```
*****
Report : power
    -analysis_effort medium
Design : ALARM_BLOCK
Version: v3.2a
Date   : Sun Jun 19 15:45:24 1994
*****
```

Library(s) Used:

power_libdb (File: /remote/libraries/power_lib.db)

Operating Conditions:

report_power_calculation

Displays the calculation of the internal power for a pin, the leakage power for a cell, or the switching power for a net.

SYNTAX

```
int report_power_calculation
pin_cell_or_net_list
[-state_condition boolean_eq_of_pins | default | all]
[-path_source pin_name | default | all]
[-rise]
[-fall]
[-verbose]
[-nosplit]
```

Data Types

<i>pin_cell_or_net_list</i>	object_list
<i>boolean_eq_of_pins</i>	string
<i>pin_name</i>	string

ARGUMENTS

pin_cell_or_net_list

Specifies the objects on which the power calculation reports. All objects in the list must be of the same type. The type of power calculation depends on the object type, as follows:

- The tool reports the internal power calculation for a pin.
- The tool reports the leakage power calculation for a cell.
- The tool reports the switching power calculation for a net.

-state_condition boolean_eq_of_pins | default | all

Reports only the tables or polynomials with matching state conditions. This option is valid only for pin or cell type objects. Use **-state_condition default** to specify the default state condition. Use **-state_condition all** to consider all states for reporting.

-path_source pin_name | default | all]

Reports only the tables or polynomials with matching path sources. This option is valid only for pin type objects. Use **-path_source default** to specify the default path condition (no path source). Use **-path_source all** to specify that all path sources must be considered for reporting.

-rise

Limits the report of internal power calculation to only the rise power.

-fall

Limits the report of internal power calculation to only the fall power.

```

-verbose
    Increases the amount of information that is reported for cells or pins. For
    cells, the leakage power calculation report is appended by an internal power
    calculation report for all pins and all possible states and path sources of
    the cells in the object list. For pins, all of the possible states and paths
    are printed (equivalent to specifying -state_condition all -path_source all).

-nosplit
    Prevents line-splitting and facilitates writing software to extract
    information from the report output. Most of the design information is listed
    in fixed-width columns. If the information for a given field exceeds its
    column's width, the next field begins on a new line, starting in the correct
    column.

```

DESCRIPTION

The **report_power_calculation** command provides detailed power calculation information for the specified pin, cell, or net. Use this information for debugging or verifying power data in a technology library. Before using this command to display details of internal or leakage power calculation, read the technology library file into the system using the **read_lib** command. This command automatically compiles the library and enables the **report_power_calculation** command for internal and leakage power. Otherwise, the built-in security mechanism terminates the command when issued for pin internal power or cell leakage power calculation. This restriction does not apply to net switching power calculation.

It is considered best practice to use the **report_power** command before issuing **report_power_calculation**. This ensures the propagation of any missing switching activity. If the design is not completely annotated with switching activity when **report_power_calculation** is executed, the missing activity is propagated with the same analysis effort that was used during the last issued **report_power** command. If no power analysis is performed prior to issuing the **report_power_calculation** command, a low analysis effort is used for switching activity propagation.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows the calculation of path dependent internal power from input pin B to output pin Y. The contributions for rise and fall internal power are shown separately.

```

prompt> report_power_calculation U4/Y -state default -path B

*****
Report : power_calculation
          U4/Y
          -state_condition default
          -path_source B
Design  : rpc

```

report_power_domain

Reports information about the specified power domain.

SYNTAX for UPF Mode

```
status report_power_domain
```

```
[power_domains]
[-scope instance_name]
[-operating_condition]
```

Data Types for UPF Mode

```
power_domains      list
instance_name      string
```

SYNTAX for Non-UPF Mode

```
status report_power_domain
```

```
[power_domains]
```

Data Types for Non-UPF Mode

```
power_domains      list
```

ARGUMENTS

`power_domains`

Specifies the power domains to be reported. The option value can be a collection of power domains or name patterns.
The command fails if it does not find the specified power domain.
In UPF mode, if this option is not specified, the command reports all power domains in the specified scope, or the current scope, if none is specified.
In non-UPF mode, if this option is not specified, the command reports all power domains in the current design.

`-scope instance_name`

This option is available only in UPF mode.
Specifies the scope in which the power domain is to be reported. The instance name is the name of a hierarchical cell.
If this option is not specified, the power domain is reported for the current scope.
If this option is specified, the `power_domains` list must be a simple name, not a collection.

`-operating_condition`

This option is available only in UPF mode.
Reports the operating conditions. If the design is not a multivoltage design, no operating conditions are reported.

DESCRIPTION

The **report_power_domain** command enables you to get detailed information about existing power domains. If you specify the power domains, only those power domains are reported; otherwise all power domains in the current scope (UPF mode) or current design (non-UPF mode) are reported.

The following information is reported for each power domain:

- The hierarchical name relative to the current scope
- The current scope
- The elements of the current scope
- The supply nets available for use (supply nets that are not domain supply nets, a part of any isolation or retention strategies, and connected to switches)
- The primary power and ground net
- The isolation strategies and the isolation power and ground nets,
- The retention strategies and its retention power and ground nets,
- The power switches
- The input and output supply nets
- The maximum voltage of each supply net is reported if it has been set by the **set_voltage** command.
- If the **-operating_condition** option is used, then operating conditions are also reported.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

`connect_power_domain(2)`
`create_power_domain(2)`
`remove_power_domain(2)`

report_power_gating

Reports the power gating style of retention registers in the design.

SYNTAX

```
int report_power_gating  
[cell_or_design_list]  
[-missing]  
[-unconnected]
```

Data Types

cell_or_design_list list

ARGUMENTS

cell_or_design_list

Specifies a list of cells or designs in which the power gating styles of cells are reported. The default is the current design.

-missing

Reports the sequential cells which don't have the power gating style.

-unconnected

Only reports the retention registers that are not stitched.

DESCRIPTION

This command reports the power gating style of retention registers. The retention registers in the libraries have a cell level attribute *power_gating_cell* to specify the power gating styles of the registers. The command only reports the cells having the *power_gating_style* attributes set by *set_power_gating_style* command. It requires a Power Compiler license to run.

If -missing is specified, the command will only report the sequential cells which don't have the power gating style.

If -unconnected is specified, the command will only report the retention registers whose power gating pins have not been stitched yet.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example indicates that the power gating styles of retention registers in design *FOO* will be reported.

```
prompt>report_power_gating FOO
```

SEE ALSO

```
set_power_gating_style(2)
power_enable_power_gating(3)
```

report_power_guidefp

Reports existing power guides with different information.

SYNTAX

```
report_power_guidefp
[power_guide_list]
```

ARGUMENTS

power_guide_list

The list of power guides to be reported. This is optional.

DESCRIPTION

The command **report_power_guide** reports the given power guides. If no specific power guide is given, all existing power guides will be reported.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example output of report_power_guide command :-

```
prompt> create_bounds -name AO_WELL -coordinate {10 10 20 20} -exclusive
prompt> create_voltage_area -name VA_SHUTDN -coordinate {5 5 30 30}
                  [get_cells A_INST]
prompt> set_power_guide -name AO_WELL
prompt> report_power_guide AO_WELL
*****
Report Power Guide
*****
Name      : AO_WELL

set_power_guide(2)
unset_power_guide(2)
```

report_power_net_info

Reports the power net information for the current design.

SYNTAX

```
integer report_power_net_info
```

ARGUMENTS

The **report_power_net_info** command has no arguments.

DESCRIPTION

The **report_power_net_info** command reports the power net information for the current design.

EXAMPLE

The following example creates the power domain and then uses **report_power_net_info** to report the information:

```
prompt> create_power_domain T
1
prompt> create_power_net_info T_VDD -power
1
prompt> create_power_net_info T_VSS -gnd
1
prompt> create_power_domain T
1
prompt> connect_power_domain T -primary_power_net T_VDD \
      -primary_ground_net T_VSS

Internal Ground Hookups: T

1

SEE ALSO

`create_power_net_info(2)`
`connect_power_domain(2)`

report_power_options

Reports different power optimization options.

SYNTAX

```
status report_power_options
```

ARGUMENTS

None.

DESCRIPTION

The **report_power_options** command reports power optimization options.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the use of the command.

```
report_power_options
```

SEE ALSO

```
set_power_options(2)
```

report_power_pin_info

Reports the power pin information for technology library cells or leaf cells. In UPF mode, the command reports power pin information only for instantiated cells and not the library cells.

SYNTAX

```
status report_power_pin_info
object_list
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of technology library cells or a list of leaf cells. Library cells are not allowed as arguments in UPF mode.

DESCRIPTION

The **report_power_pin_info** command reports the power pin information for technology library cells or leaf level cells in the current design.

When a list of library cells is specified, the name, the types and the voltage specification of the power pins are reported. Library cells are not allowed as arguments in the UPF mode.

When a list of leaf cells is specified in the *object_list*, the supply (power and ground) nets that are connected to the power pins are also reported. If a supply connection is marked with an asterisk (*), it is an exception (explicit) connection. Exception supply connections are connections that are established with the **connect_supply_net** command in UPF mode, or with the **connect_power_net_info** command in non-UPF mode.

Exception supply connections can occur in the following situations:

- Explicit specification of the **connect_supply_net** or **connect_power_net_info** command in UPF mode and non-UPF mode, respectively.
- Power intent specification in the UPF file.
- Level-shifter cell insertion during compilation.

In any of these cases you can observe the exception connections using the **write_script** or **save_upf** commands. The connections appear as **connect_supply_net** (or **connect_power_net_info** in non-UPF mode) in the files written out.

In UPF mode, the best-case and worst-case voltages of the connected power net are reported, along with the name of the power net. If a voltage is not specified on the

connected net, a hyphen (-) is printed in the respective voltage fields.

Hierarchical cells are ignored by this command. In UPF mode, the tool issues the message "No power pins to report".

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports power pin information in UPF mode:

```
prompt> fbreport_power_pin_info
*****
Report : power_pin_info
Design : top
Version: B-2008.09
Date   : Mon Mar 24 02:04:49 2008
*****
```

Note: Power connections marked by (*) are exceptional

```
-----

`connect_power_net_info(2)`
`connect_supply_net(2)`
`disconnect_power_net_info(2)`

report_power_switch

Reports all of the specified power switches. This command is supported only in UPF mode.

SYNTAX

```
status report_power_switch
[-verbose]
```

ARGUMENTS

-verbose
Reports details about the specified power switches.

DESCRIPTION

The *report_power_switch* command enables you to get the information of the specified power switches. The power switch information reported includes its relative hierarchical name that also contains the scope in which it is created, the current scope name, the name of the simple power domain of which the switch is a part, its output supply net, and its input supply net.

The command also prints out a verbose report if the **-verbose** switch is present. The verbose report contains all of the information specified above along with the ctrl_port names, the ack_port names, and the on and off state names with their respective Boolean functions.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports information about all power switches within the power domain named PD1 in the current scope:

```
prompt> report_power_switch SWA
-----
```

```
Power Switch          : SWA
Current Scope         : midi1
Switch Power Domain   : A
Input port net        : SNA_2
Output port net       : SNA_1
```

```
-----  
1
```

The following example reports the information about the same power switches as

above, this time using the **-verbose** option to show more detail:

```
prompt> report_power_switch SWA -verbose
-----
Power Switch          : SWA
Current Scope         : mid1
Switch Power Domain   : A
Input port net        : SNA_2
Output port net       : SNA_1
Control Ports         : ctrl
Acknowledge Ports     : ackport1, ackport2

On States             : <on1, ctrl>, <on2, !logic1 & ctrl>,
                        <on3, !logic1 & !ctrl>, <on4, !logic1 | ctrl>,
                        <on5, !logic1 | !ctrl>
Off States            : <off1, outport>, <off2, outport>
-----
```

1

SEE ALSO

`remove_power_switch(2)`

report_preferred_routing_direction

Reports the preferred routing direction for all routing layers.

SYNTAX

```
string report_preferred_routing_direction
```

ARGUMENTS

The **report_preferred_routing_direction** command has no arguments.

DESCRIPTION

The **report_preferred_routing_direction** command reports the preferred routing direction for all layers from in-memory information.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example of a preferred routing direction report:

```
prompt> report_preferred_routing_direction
*****
Report : Layers
Design : core_chip
Version: Y-2006.06
Date   : Thu Mar 23 03:43:06 2006
*****

report_preroute_drc_strategy

Reports preroute drc options set in `set_preroute_drc_strategy` to change the internal rules in the following PG commands: `create_rectangular_rings`, `create_pad_rings`, `create_power_straps`, `create_preroute_vias`, `preroute_instances`, `preroute_standard_cells`. These settings are not persistent in the Milkyway design.

SYNTAX

```
status report_preroute_drc_strategy
```

ARGUMENTS

The `report_preroute_drc_strategy` command has no arguments.

DESCRIPTION

Reports preroute drc options set in `set_preroute_drc_strategy` to change the internal rules in the following PG commands: `create_rectangular_rings`, `create_pad_rings`, `create_power_straps`, `create_preroute_vias`, `preroute_instances`, `preroute_standard_cells`. Recommended to check how DRC rules are applied in the above commands.

The reported options have the following meaning:

DRC spacing: Specifies the mode for design rule checking, either *radial* or *manhattan*. A *radial* rule checks for spacing violations within a circular area. A *manhattan* rule checks for spacing violations within the defined spacing distance horizontally and vertically.

Protect pin access edge: If True (1), it will prevent the Signal Pin Access Edge from being blocked by the Prerouter.

Treat fat blockages as fat: If True (1), fat blockages are treated as fat wires. Otherwise, design rule checking treats fat blockages as thin wires.

Use fat vias if wires meet width requirements: If True (1), fat vias will be used for non-turning layer changes if either wire meets the width requirement for fat vias.

Ignore contents of std cell pins in DRC checking: If True (1), design rule checking is not done for objects in standard cells. RISKY!

Ignore top level pins in DRC checking: If True (1), design rule checking is not done for top-level pins. RISKY!

Ignore same net metal-metal in DRC checking: If True (1), design rule checking ignores same net metal-to-metal rule. RISKY!

Quick DRC check: If True (1), design rule checking skips certain rules. RISKY!

Merge thin wires in DRC checking: If True (1), prerouter checks and merges thin

wires into fat wires for design rule checking. SLOW!

Turn off all DRC check: If True (1), no design rule checking is done. EXTREMELY RISKY!

Report detailed info about failed connections: If True (1), detailed information about the failed PG command operation is reported.

Range within which prerouter may perform jogging: If greater than 0, a jogging range distance within which the prerouter might perform limited jogging, is set. Jogging range defines the maximum distance for a dogleg connection on the same layer, it is not for layer switching.

Min metal layer to be used by prerouter: Shows the minimum metal layer used for prerouting.

Max metal layer to be used by prerouter: Shows the maximum metal layer used for prerouting.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
report_preroute_drc_strategy

Current Preroute DRC options
-----
DRC spacing = Radial
Protect pin access edge = 0
Treat fat blockages as fat = 0
Use fat vias if wires meet width requirements = 0
Ignore contents of std cell pins in DRC checking = 0
Ignore top level pins in DRC checking = 0
Ignore same net metal-metal in DRC checkin = 0
Quick DRC check = 0
Merge thin wires in DRC checking = 0
Turn off all DRC check = 0
Report detailed info about failed connections = 0
Range within which prerouter may perform jogging = 0

report_primestime_options

Reports the PrimeTime options for the **signoff_opt** command.

SYNTAX

```
status report_primestime_options
```

ARGUMENTS

This command does not take any arguments.

DESCRIPTION

report_primestime_options command to examine the options which are set by **set_primestime_options** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example runs the **report_primestime_options** command.

```
prompt> open_mw_cel -lib my_lib my_cel
prompt> report_primestime_options
*****
Report : PrimeTime_options
Design : my_design
Version: X-2005.12-ICC
Date   : Mon Aug 15 15:55:58 2005
*****
PrimeTime exec dir: /PrimeTime/linux/syn/bin
```

SEE ALSO

```
set_primestime_options(2)
signoff_opt(2)
place_opt(2)
clock_opt(2)
route_opt(2)
```

report_pst

Report power states in current design (UPF mode only).

SYNTAX

```
int report_pst
[-verbose]
[-supplies supply_list]
[-scope instance_name]
[-power_nets supply_net_list]
[-compress]
[-trace_name]
[-significant_digits digit]
[-width line_width]
[-column_space column_space]
[-derived]
```

Data Types

<i>supply_list</i>	list
<i>instance_name</i>	string
<i>digit</i>	integer

ARGUMENT

-verbose

All power states will be reported explicitly even when all power state of a net or port are listed in the PST. By default, the PST shows '*' when all states of nets or ports are used.

-supplies *supply_list*

A list of supply net or port names to be included in the report. The order of power nets in this list also determines the order they are shown in the report. By default, all power nets in current design are included.

-scope *instance_name*

Specifies a design instance different from current design. The resulting PST contains the supply states derived from all PST contained in the specified design instance.

-power_nets *supply_net_list*

Same as '-supplies' argument. To be obsolete in the next service pack.

-compress

Ignored. To be removed in the next service pack.

-trace_name

Ignored. To be removed in the next service pack.

-significant_digits *digit*

Ignored. To be removed in the next service pack.

```
-width line_width
      Ignored. To be removed in the next service pack.
```

DESCRIPTION

This command reports the resulting power state table (PST) of the current design. The resulting PST is combined by all user PSTs contained in the current design or in its logical hierarchy.

If the PST has not been created, the power state table is full, meaning that any power state is allowed. Once the PST is created, the table becomes empty and new power states could be created and added to the table by the command of `add_pst_state`.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

`create_pst(2)`
`add_port_state(2)`
`add_pst_state(2)`

report_qor

Displays QoR information and statistics for the current design.

SYNTAX

```
status report_qor
[-significant_digits digits]
[-physical]
[-scenario scenario_list]
```

Data Types

<i>digits</i>	integer
<i>scenario_list</i>	list

ARGUMENTS

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are reported. Allowed values are from 0 through 13. The default is 2 for all sections except the Area section, which has a default of 6. Specifying a valid value for significant digits overwrites the existing default value. Using this option overrides the value set by the **report_default_significant_digits** variable.

-physical

Reports a QoR metrics snapshot.

-scenario *scenario_list*

Reports the QoR for the specified list of scenarios of a multi-scenario design. Inactive scenarios are skipped in the report. Each scenario is reported separately. If this option is not specified, the command reports the QoR on all scenarios.

DESCRIPTION

This command reports information on timing path group details and cell count, and current design statistics including combinational, non-combinational, and total area. The command also reports static power, design rule violations, and compile time details.

Under the Cell Count section, the Leaf Cell Count reported includes all leaf cells that are not constant cells. Constant cells are omitted in this count.

Multicorner-Multimode Support

This command uses information from active scenarios only.

This command supports an option to specify which active scenarios it should work with.

EXAMPLES

The following is an example of a QoR report:

SEE ALSO

`report_default_significant_digits(3)`

report_qor_snapshot

Reports existing QoR snapshot of timing, DRC, area, clock, power, etc. The report utility gets snapshot information from the location specified by the **icc_snapshot_storage_location** variable.

NOTE: This is the new version of the **report_qor_snapshot** command that supports both multicorner-multimode designs as well as non-multicorner-multimode designs.

SYNTAX

```
void report_qor_snapshot  
[-name name]  
[-display]  
[-save_as report_name]
```

Data Types

name string

ARGUMENTS

```
-name name  
      Specifies the name of the QoR snapshot to be reported.  
  
-display  
      An interactive brower will pop up and allow users to navigate through  
      individual snapshot(s). The interactive browser is defined by variable  
      gui_online_browser.  
  
-save_as report_name  
      Specified the name of the report. The report will be saved under this name,  
      users then can access the report at a later time.
```

DESCRIPTION

This command reports all of the available QoR snapshots under design_dir/snapshot. If no snapshot exists, a message is displayed.

The **-name** option specifies which snapshot to be reported. If **-name** is not specified, all saved snapshots are shown.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

In the following example, **report_qor_snapshot** will report QoR snapshot named *preroute* which is saved under design/snapshot directory.

```
report_qor_snapshot  
1900
```

```
prompt> report_qor_snapshot -name preroute
```

report_qtm_model

Reports Quick Timing Model (QTM) data.

SYNTAX

```
string report_qtm_model
[-global_parameters]
[-ports]
[-arcs]
```

ARGUMENTS

-global_parameters	Specifies that global parameters of the current QTM design be reported.
-ports	Specifies that ports of the current QTM design be reported.
-arcs	Specifies that timing arcs of the current QTM design be reported.

DESCRIPTION

The **report_qtm_model** command prints a report of the active QTM model. The information details the global parameters, ports, and arcs of the QTM model. By default, the command prints out the report of global parameters, ports, and arcs of the model.

If you want to see the global parameters in the QTM model, use the **-global_parameters** option.

If you want to see only the ports in the QTM model, use the **-ports** option.

If you want to see the arcs in the QTM model, use the **-arcs** option.

For a basic description of QTM, see the **create_qtm_model** manual page. For a more detailed description of QTM, see the *ICC Design Planning User Guide*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command reports all the attributes of the currently active QTM model.

```
prompt> report_qtm_model
*****
report_qtm_model
1902
```

```

Report : qtm_model

report_rail_options

Reports the current option settings of the **analyze_rail** command.

SYNTAX

```
report_rail_options
```

ARGUMENTS

The **report_rail_options** command has no arguments.

DESCRIPTION

Prints out the current option settings of the **analyze_rail** command.

EXAMPLE

The following example reports the current option settings for the **analyze_rail** command:

```
prompt> report_rail_options
*****
Report : rail_options
Design : micro
Version: C-2009.06
Date   : Mon Feb 23 23:12:55 2009
*****

```

SEE ALSO

`set_rail_options(2)`
`analyze_rail(2)`

report_reference

Displays information about references in the current instance or in the current design.

SYNTAX

```
integer report_reference
[-nosplit]
[-hierarchy]
```

ARGUMENTS

-nosplit
Prevents line-splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-hierarchy
Displays information about references across the hierarchy in the current instance or the current design.

DESCRIPTION

Displays information about all references in the current instance or the current design. If the current instance has been set, the report is generated for the design of that instance. Otherwise the report is generated for the current design.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following is an example of a reference report:

```
prompt> report_reference

SEE ALSO

```

report_cell(2)
report_design(2)

```

report_retention_cell

Displays information about retention cells in the current scope. This command is supported only in UPF mode.

SYNTAX

```
status report_retention_cell
[retention_cells]
[-domain power_domains]
[-verbose]
[-strategy a_list_of_strategies]
```

Data Types

<i>retention_cells</i>	list
<i>power_domains</i>	list

ARGUMENTS

retention_cells
Specifies the retention cells that are to be reported. If the specified cells do not exist in the current scope, the command fails. By default, all retention cells in the current scope are reported when no other options are specified.

-domain *power_domains*
Specifies the power domains to report all retention cells in the design belonging to the power domains. If the specified power domains do not exist in the current scope, the command fails.

-verbose
Reports retention strategy details in addition to information about the retention cells.

DESCRIPTION

The **report_retention_cell** command provides detailed information of all retention cells in the current scope. If the **-domain** option is specified, the tool reports on all retention cells in the specified domains. If the **-retention_strategy** option is specified, the tool reports on all retention cells under the specified strategy for the given power domain.

The report shows the instance name of the retention cell, the library reference name of the retention cell, and the retention strategy. If the **-verbose** option is specified, the report also shows the details of the retention strategy, which include the name of the retention strategy, the names of the save and restore signals, the save sense and restore sense values, and the names of the power and ground nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the information about all of the retention cells in the current scope:

```
prompt> report_retention_cell
```

```
-----

report_route_opt_strategy

Reports the parameters that influence route_opt flow.

SYNTAX

```
int report_route_opt_strategy
```

ARGUMENTS

The **report_route_opt_strategy** command has no arguments.

DESCRIPTION

The **report_route_opt_strategy** command reports the parameters that influence route_opt in optimization and routing.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **report_route_opt_strategy** command.

```
prompt>set_route_opt_strategy -effort high
```

```
prompt> report_route_opt_strategy
```

```
***** route_opt strategy for the
design: Route Mode : Timing Fix Hold Mode : route_base Search-Repair loops : 10 ECO
Search-Repair loops : 5 Optimize Wire/Via Search-Repair loops : 5 Optimize Wire/Via

*****
```

SEE ALSO

```
set_route_opt_strategy(2)
```

report_route_options

Report settings of route options that are shared (in common) among multiple router commands.

SYNTAX

```
status report_route_options
[-default]
```

ARGUMENTS

```
-default
Reports default options.
```

DESCRIPTION

This command reports the settings of router parameters that have been set by the **set_route_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the use of the command.

```
prompt> report_route_options
```

SEE ALSO

```
set_route_options(2)
```

report_route_zrt_common_options

Reports the settings of route options that are common among the Zroute router commands.

SYNTAX

```
status report_route_zrt_common_options
```

ARGUMENTS

The **report_route_zrt_common_options** command has no arguments.

DESCRIPTION

This command reports the settings of router options that have been set by the **set_route_zrt_common_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command reports the settings of the common route options.

```
prompt> report_route_zrt_common_options
```

SEE ALSO

```
set_route_zrt_common_options(2)  
get_route_zrt_common_options(2)
```

report_route_zrt_detail_options

Reports the settings of the detail router options.

SYNTAX

```
status report_route_zrt_detail_options
```

ARGUMENTS

The **report_route_zrt_detail_options** command has no arguments.

DESCRIPTION

This command reports the settings of the detail router options that have been set by the **set_route_zrt_detail_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command reports the settings of the detail router options.

```
prompt> report_route_zrt_detail_options
```

SEE ALSO

`get_route_zrt_detail_options(2)`

report_route_zrt_global_options

Reports the settings of the global router options.

SYNTAX

```
status report_route_zrt_global_options
```

ARGUMENTS

The **report_route_zrt_global_options** command has no arguments.

DESCRIPTION

This command reports the settings of the global router options that have been set by the **set_route_zrt_global_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the global router settings.

```
prompt> report_route_zrt_global_options
```

SEE ALSO

`get_route_zrt_global_options(2)`
`set_route_zrt_global_options(2)`

report_route_zrt_track_options

Reports the settings of track assignment options.

SYNTAX

```
status report_route_zrt_track_options
```

ARGUMENTS

None.

DESCRIPTION

This command reports the settings of track assignment options that have been previously set by using the **set_route_zrt_track_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the track assignment options.

```
prompt> report_route_zrt_track_options
```

SEE ALSO

`get_route_zrt_track_options(2)`
`set_route_zrt_track_options(2)`

report_routing_rules

Reports design-specific nondefault routing rules defined by the **define_routing_rule** command and their current values.

SYNTAX

```
integer report_routing_rules  
rule_name
```

Data Types

```
rule_name      string
```

ARGUMENTS

```
rule_name  
      Specifies the name of the design-specific nondefault routing rule to report.  
      By default, the tool reports all design-specific nondefault routing rules.
```

DESCRIPTION

This command reports design-specific nondefault routing rules defined by the **define_routing_rule** command and their current values. (It does not report rules defined in the physical library.)

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the design-specific nondefault rule named *WideMetal*.

```
prompt> report_routing_rules WideMetal
```

SEE ALSO

```
define_routing_rule(2)  
set_net_routing_rule(2)
```

report_rp_group_options

Reports relative placement group attributes on the specified relative placement groups.

SYNTAX

```
status report_rp_group_options  
rp_groups
```

Data Types

rp_groups collection or list

ARGUMENTS

rp_groups

Specifies the relative placement groups for which you want to report the attributes. If relative placement groups are not specified, the attributes for all relative placement groups will be reported.

DESCRIPTION

The **report_rp_group_options** command reports the attributes of the specified relative placement groups. The attributes were set by using either the **create_rp_group** or the **set_rp_group_options** command.

This command is supported only for designs that do not contain multiply-instantiated designs.

Relative placement usage is available with Design Compiler Ultra.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **report_rp_group_options** to report the attributes for a relative placement group:

```
prompt> report_rp_group_options {example3::top_group example3::block2}
```

```
*****  
Report : The RP group options.  
Design : example3

*****
```

```
RP group: example3::top_group
utilization      : 1.000000
ignore          : FALSE
x_offset        : 0
y_offset        : 0
cts_option     : fixed_placement
RP group: example3::top_group
utilization      : 1.000000
ignore          : FALSE
1
```

SEE ALSO

`create_rp_group(2)`
`set_rp_group_options(2)`

report_saif

Reports statistics on the switching activity annotation on the current design or instance.

SYNTAX

```
int report_saif
[-hier]
[-flat]
[-type rtl | gate]
[-rtl_saif]
[-missing]
[-only cell_or_net_list]
[-annotated_flag]
```

Data Types

cell_or_net_list object_list

ARGUMENTS

-type rtl | gate
Specifies whether switching activity annotations are to be reported for objects annotated by an RTL backward SAIF file or a gate-level backward SAIF file.
An RTL backward SAIF file is generated using RTL simulation, and contains the switching activity of synthesis invariant objects. These are objects that do not change during synthesis, and include the design ports, and the outputs of sequential and three-state cells. Calling the **read_saif** command with **-type rtl** reports the switching activity annotation on design ports, sequential cell outputs, and three-state outputs. Use the **-type rtl** argument after reading an RTL backward SAIF.
A gate-level backward SAIF file is generated using gate-level simulation, and contains the switching activity of all design nets. Calling the **read_saif** command with **-type gate** reports the switching activity annotation on the design ports, nets, and leaf cell pins. Use the **-type gate** argument after reading a gate-level backward SAIF file.
When the **-type** argument is not used, the default **-type gate** is assumed.

-rtl_saif
Specifies that switching activity annotations are to be reported for objects annotated by an RTL backward SAIF file.
Specifying the **read_saif** command with the **-rtl_saif** flag is equivalent to running the command with **-type rtl**.

-missing
Specifies that the report lists the design elements that do not have user switching activity annotation. This report does not include constant value nets (logic one/zero nets) and pins and ports connected to such nets. This type of nets, pins, and ports are annotated with default switching activity if they are not user annotated.

```
-only cell_or_net_list
    Specifies that switching activity annotation is to be reported only for the
    specified object list.

-annotated_flag
    Specifies that the report lists the design elements that have user-annotated
    switching activity.
```

DESCRIPTION

The **report_saif** command reports the switching activity annotation on the nets, ports, and cells in the current design or instance.

The **report_saif** command can be used to display switching activity annotation of synthesis invariant objects by using the **-rtl_saif** flag or the equivalent **-type rtl** argument. If these options are not used, then **report_saif** displays information on the design ports, nets, and non-hierarchical cell pins.

The report generated by **report_saif** lists the percentage of objects with switching activity that is user-annotated, default-annotated and propagated. Switching activity can be annotated by the user by the **set_switching_activity**, **read_saif**, and **merge_saif** commands.

During power calculations, the tool estimates the switching activity of objects that are not user-annotated by propagating the user or default annotated switching activity. Switching activity is annotated with default values on objects whose switching activity can be derived accurately, such as clocks and nets driven by constants, or on objects that cannot be annotated using the propagation mechanism, such as the design primary inputs and outputs of black-box cells. Switching activity is default annotated and propagated automatically by the **report_power** command.

Propagated switching activity is less accurate than switching activity obtained by simulation, so the percentage values in the user-annotated column of the report generated by **report_saif** are an indication of the accuracy of power reports.

Multicorner Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The examples below report switching activity for the current design.

In the following example, the **report_saif** command is used after the **read_saif** command on a gate-level design. With the **-missing** option set, the report lists the nonannotated ports, nets, and pins.

```
prompt> report_saif -hier -missing
```

```
*****
Report : saif
-gate
```

```
-flat

report_scan_chain

Reports the scan chains defined on the current design.

SYNTAX

```
status report_scan_chain
```

ARGUMENTS

The **report_scan_chain** command has no arguments.

DESCRIPTION

This command reports all scan chain information. The chains are defined on the current open CEL.

Using SCANDEF data, the report displays the chain's start and the stop port or pin, partition label, validation status, and all scan chain components.

The status can be NOT YET VALIDATED, VALIDATED/V or FAILED/F.

- NOT YET VALIDATED indicates that the **check_scan_chain** command has not been run to determine the status.
- VALIDATED indicates that the SCANDEF data in the report is consistent with the netlist.
- FAILED indicates an inconsistency between the SCANDEF data and the netlist.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example of a scan chain report:

```
prompt> report_scan_chain
*****
Report : Scan Chain
Design : CORE
Version: W-2004.12
Date   : Thu Jun  2 14:02:00 2005

```

report_scenario_options

Reports the scenario options set by the **set_scenario_options** command.

SYNTAX

```
status report_scenario_options  
[-scenarios scenario_list]
```

ARGUMENTS

-scenarios scenario_list

Specifies a list of scenarios, active or inactive, to be reported. By default, the command reports scenario options for the current scenario.

DESCRIPTION

This command reports the values of scenario options set using the **set_scenario_options** command, for the current scenario or the scenarios listed using the **-scenarios** option. This command can report scenario options for inactive scenarios as well, except for leakage_only and hold_only scenarios.

EXAMPLES

The following example uses **report_scenario_options** command to check the settings for the current scenario:

```
prompt> create_scenario MODE1  
Warning: Discarding all scenario specific information previously defined in  
this session. (UID-1008)  
Current scenario is: MODE1  
1  
  
prompt> set_scenario_options -setup false

report_scenarios

Reports scenarios setup information for multi-scenario design.

SYNTAX

```
int report_scenarios
```

ARGUMENTS

None.

DESCRIPTION

The **report_scenarios** command reports scenarios setup information for multi-scenario design. It will report all defined scenarios, all active scenarios, current scenario, CTS scenario and leakage only scenario setting information and other scenario specific information for active scenarios. The scenario specific information includes library used in linking for the scenario, design operating condition for the scenario and tlu plus files for the scenario.

Multicorner-Multimode Support

This command uses information from inactive scenarios only.

EXAMPLES

The following example shows the sample output of **report_scenarios**.

```
prompt>report_scenarios

*****

```

report_si_options

Reports signal integrity options used for analysis or optimization.

SYNTAX

```
int report_si_options
```

ARGUMENTS

None.

DESCRIPTION

This command reports signal integrity options used for analysis or optimization.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to use this command.

```
prompt> report_si_options
*****
Report : si options

*****
```

SEE ALSO

`set_si_options(2)`

report_signal_em

Reports signal electromigration results for the violating or specified nets. Also generates a repair file consisting of variable routing rules that can be loaded into the database for rerouting.

SYNTAX

```
status report_signal_em
[-healing_factor healing_factor_value]
[-violation_rule_type mean | abs_avg | rms | peak | auto]
[-repair_file repair_file_name]
[-min]
[-max]
[-violated]
[-verbose]
[list_of_nets]
```

ARGUMENTS

-healing_factor *healing_factor_value*

The healing factor is used for calculating the average current. The default is 1.0.

-violation_rule_type mean | abs_avg | rms | peak | auto

Reports the current density values using only the specified rule. If **auto** is selected, the report includes all the rules for which there are constraints defined in the database. The default is **auto**.

-repair_file *repair_file_name*

Specifies the name of the file to which you want to write the variable routing rules for interconnect electromigration repair.

-min

Uses minimum corner timing values to calculate the current density. If neither **-min** nor **-max** is specified, both minimum and maximum values are calculated.

-max

Uses maximum corner timing values to calculate current density. If neither **-min** nor **-max** is specified, both minimum and maximum values are calculated.

-violated

Reports only violating nets. If you specify the *list_of_nets* argument, it reports only the violating nets among the specified nets. Otherwise, it reports all the violating nets in the design.

-verbose

Reports additional information for all specified nets or violating nets, including layer name, Rel_AbsAvg, and Rel_RMS.

DESCRIPTION

The **report_signal_em** command provides a report of signal (interconnect) electromigration information for the current design.

The command performs electromigration analysis of each net by calculating the current on every edge of the net and comparing it with the current thresholds defined in the design library. It also generates a repair file consisting of variable routing rules that can be loaded into the database for rerouting.

Current density information is not saved as net attribute. Each time you run the **report_signal_em** command, the tool calculates the current density for each specified net.

Before running **report_signal_em**, make sure the design has signal electromigration constraints defined in the Milkyway design library. You can use Library Compiler or the Milkyway tool to load a

Also, be sure that switching activity has been defined for all boundary nets.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows a signal electromigration report for net "n1" using both minimum and maximum corners. The rule type is RMS and the repair file name is "foo".

```
prompt> report_signal_em -repair "foo" [get_nets n1]
```

SEE ALSO

```
read_saif(2)  
set_switching_activity(2)
```

report_skew_group

Reports the user-defined skew groups in the design.

SYNTAX

```
status report_skew_group
[-clock clock_name]
[-name skew_group_name]
```

Data Types

<i>clock_name</i>	string
<i>skew_group_name</i>	string

ARGUMENTS

```
-clock clock_name
      Reports only the skew groups that are on the specified clock path.

-name skew_group_name
      Reports the skew group parameters of the specified skew group.
```

DESCRIPTION

The command reports the user-defined skew groups in the design. If you specify the **-clock** option, the command reports the skew groups that are on the specified clock path. To report the skew group with a specific name, use the **-name** option.

By default, the command lists all user-defined skew groups in the design.

EXAMPLES

The following example lists all skew groups that are on clock path clk1.

```
prompt> report_skew_group -clock clk1
CTS: Marking Ignore Pins.....
*****

report_spacing_rules

Reports inter-cell spacing rules from the library.

SYNTAX

```
status report_spacing_rules
-all
| -of_library_cells {library_cell_collection}
```

ARGUMENTS

-all
Reports all inter-cell spacing rules in the current design.

DESCRIPTION

This command reports inter-cell spacing rules that have been set with commands `set_lib_cell_spacing_label` and `set_spacing_label_rule` in the current design. One option of `-all` or `-of_library_cells` is required.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows inter-cell spacing report

```
prompt> report_spacing_rules -all

*****
* Report: inter-cell spacing constraints

report_starrcxt_options

Reports Star-RCXT options for the **signoff_opt** command.

SYNTAX

```
status report_starrcxt_options
```

ARGUMENTS

This command does not take any arguments.

DESCRIPTION

report_starrcxt_options command to examine the options which are set by **set_starrcxt_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **report_starrcxt_options** command.

```
prompt> open_mw_cel -lib my_lib my_cel
prompt> report_starrcxt_options
*****
Report : StarRCXT_options
Design : my_design

```

report_supply_net

Reports all the supply nets in the current scope. This command is supported only in UPF mode.

SYNTAX

```
status report_supply_net
[-include_exception]
```

ARGUMENTS

-include_exception
Includes the exception connections of the supply net.

DESCRIPTION

The **report_supply_net** command reports detailed information about the supply nets in the current scope. The report for a supply net includes the following information: its full name, the scope in which it was created, its maximum and minimum voltages if set using the **set_voltage** command, its resolve type, the various supply states and the exception pins on the power net if the **-include_exception** option is specified. The names of the power domains to which the supply net belongs are also printed. The name of the power domain is suffixed with an asterisk (*) if the net is set as the domain supply net for that domain.

If the voltage of the supply net is not set, a '- U -' is printed, indicating that the voltage is undefined.

This command returns 1 on success, 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports information about the supply nets SN1 in the current scope.

```
prompt> report_supply_net

*****
Report : supply_net
Design : top
Version: A-2007.12-SP1
Date   : Wed Nov 21 03:15:21 2007
*****
```

```
Supply Net          : SN1
Current Scope      : top
Operating Voltage  : -- Best Case -- -- Worst Case --
                     (1.00)           (1.33)

Supply States      : active_state, off_state
Resolve Type       : unresolved
Exception Connections: I0/PWR, I1/PWR, PD0_INST/I1/PWR
Power Domain       : T A(*)
```

1

SEE ALSO

```

set_domain_supply_net(2)
```

report_supply_port

Reports information about the supply ports in the current scope. This command is supported only in UPF mode.

SYNTAX

```
status report_supply_port
```

ARGUMENTS

The **report_supply_port** command has no arguments.

DESCRIPTION

The **report_supply_port** command enables you to get detailed information about supply ports within the current scope. If *supply_port_name* is not specified, the tool reports on all supply ports within the current scope.

The report includes the full name of the supply port, the scope in which it is created, the direction, the supply states, and the supply net to which it is connected.

Supply ports that are present on switches can be printed by specifying the argument with the switch path name, slash (/), and supply port name as follows:

```
report_supply_port switch_full_path_name/supply_port_name
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports on all supply ports in the current scope:

```
prompt> report_supply_port
*****
Report : supply_port
Design : top
Version: A-2007.12-SP1
Date   : Wed Nov 21 03:14:25 2007

Supply state names : No supply states defined for the port
```

```
-----  
1
```

SEE ALSO

`create_supply_port(2)`

report_target_library_subset

Reports target library subsets on the design.

SYNTAX

```
int report_target_library_subset  
[-object_list cells]  
[-top]
```

ARGUMENTS

-object_list cells

Specifies the cells on which the target library subset will be reported.

-top

If specified, the target library subset being specified on the root design is reported.

DESCRIPTION

Reports the target library subset on the design based on the specified options. If none of the two options are specified, it reports the target library subset setting on the entire design.

NOTE: it only reports the target library subset information which is explicitly set by the user, does not report the inherited target library subset information, does not report the information from -milkyway_reflibs from set_target_library_subset.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the target library subset for the design and for block u1.

```
prompt> report_target_library_subset -top -object_list [get_cells u1]
```

SEE ALSO

```
set_target_library_subset(2)  
remove_target_library_subset(2)  
check_target_library_subset(2)  
set_operating_conditions(2)  
target_library(3)
```

report_threshold_voltage_group

Reports the percentage of cells for each threshold voltage group in the design.

SYNTAX

```
int report_threshold_voltage_group
[cell_or_design_list]
[-verbose]
```

Data Types

cell_or_design_list list

ARGUMENTS

cell_or_design_list

Specifies a list of cells or designs on which to report the threshold voltage groups. If not specified, the report is generated on the current design.

-verbose

Lists all of the cells belonging to each threshold voltage group. If this option is omitted, the default summary report shows only the number and percentage of cells.

DESCRIPTION

This command reports the number and percentage of cells in each threshold voltage group for the specified list of cells or designs. The threshold voltage group is defined in the technology libraries with the **threshold_voltage_group** attribute on the cell, or with the **default_threshold_voltage_group** attribute on the library. You can also set the attributes on the objects using **set_attribute** command. The attributes can be any string values, but the values must be related to the threshold voltage of the cell to be meaningful.

If **-verbose** is specified, the command lists all of the cells that belong to each threshold voltage group. Without the option, the tool generates a summary that reports only the number and percentage of cells.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the summary of cells in each threshold voltage group for the current design:

```
prompt> report_threshold_voltage_group
```

```
*****
```

Threshold Voltage Group Report

Threshold Voltage Group	Number of Cells	Percentage
hvt	588	46.41%
lvt	677	53.43%

```
*****
```

SEE ALSO

`set_attribute(2)`
`set_max_leakage_power(2)`

report_tie_nets

Report tie high and tie low nets in the current design.

SYNTAX

```
status report_tie_nets
```

ARGUMENTS

The **report_tie_nets** command has no arguments.

DESCRIPTION

The **report_tie_nets** command reports all tie high and tie low nets in the current design. The command reports the number of tie high nets and the number of tie low nets, also reports the connected pin and port for each tie net.

EXAMPLES

The following example shows the output of **report_tie_nets** command.

Design has 2 tie high net(s):

```
net tin3 connects with following port(s) or pin(s):  
  tin3  
  lefstop/A
```

```
net SNPS_LOGIC1 connects with following port(s) or pin(s):  
  mid1/min2
```

Design has 2 tie low net(s):

```
net mid1/SNPS_LOGIC0 connects with following port(s) or pin(s):  
  mid1/bot1/bin1  
  mid1/S2/B
```

```
net SNPS_LOGIC0 connects with following port(s) or pin(s):  
  lefstop/B
```

report_timing

Displays timing information about a design.

SYNTAX

ARGUMENTS

-to *to_list*

Reports only the paths to the named pins, ports, or clocks. If you do not specify **-to**, the default is to report the longest path to an output port if the design has no timing constraints. If the design has timing constraints, the default is to report the path with the worst slack within each path group if **-group** is not present. If **-group** is given, the default is to report the path with the worst slack within the group specified by **-group**.

-rise_to *rise_to_list*

Same as the **-to** option, but applies only to paths **rising** at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths **captured** by **rising** edge of the clock at clock source, taking into account any logical inversions along the clock path.

-fall_to *fall_to_list*

Same as the **-to** option, but applies only to paths **falling** at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths **captured** by **falling** edge of the clock at the clock source, taking into account any logical inversions along the clock path.

-from *from_list*

Reports only the paths from the named pins, ports, or clocks. If you do not specify **-from**, the default is to report the longest path to an output port if the design has no timing constraints. If the design has timing constraints, the default is to report the path with the worst slack within each path group if **-group** is not present. If **-group** is given, the default is to report the path with the worst slack within the group specified by **-group**.

-rise_from *rise_from_list*

Same as the **-from** option, except that the path must **rise** from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths **launched** by **rising** edge of the clock at the clock source, taking into account any logical inversions along the clock path.

-fall_from *fall_from_list*

Same as the **-from** option, except that the path must **fall** from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths **launched** by **falling** edge of the clock at the clock source, taking into account any logical inversions

along the clock path.

-through *through_list*

Reports only paths that pass through the named pins, ports, or clocks. If you do not specify **-through**, the default is to report the longest path to an output port if the design has no timing constraints. If the design does have timing constraints, the default is to report the path with the worst slack within each path group if **-group** is not present. If **-group** is given, the default is to report the path with the worst slack within the group specified by **-group**.

If you specify **-through** only once, the tool reports only the paths that travel through one or more of the objects in the list. You can specify **-through** more than once in one command invocation. For a discussion of the use of multiple **-through** options, see the DESCRIPTION section.

-rise_through *rise_through_list*

This option is similar to the **-through** option, but applies only to paths with a **rising** transition at the specified objects. You can specify **-rise_through** more than once in a single command invocation. For a discussion of multiple **-through**, **-rise_through**, and **-fall_through** options, see the DESCRIPTION section.

-fall_through *fall_through_list*

This option is similar to the **-through** option, but applies only to paths with a **falling** transition at the specified objects. You can specify **-fall_through** more than once in a single command invocation. For a discussion of multiple **-through**, **-rise_through**, and **-fall_through** options, see the DESCRIPTION section.

-path *short* | *full* | *full_clock* | *full_clock_expanded* | *only* | *end*

Specifies how to display the timing path. By default, the full path is displayed. If **full_clock** is specified, the report is similar to the report you get with **full** but also reports the full clock paths for propagated clocks. If **full_clock_expanded** is specified, the report is similar to the report you get with **full_clock** but also reports the full clock path from the primary clock to the related generated clock source. If you specify **short**, only start and end points are displayed. If you specify **only**, only the path is displayed without the accompanying required-time and slack calculation. If you specify **end**, the report has a column format that shows one line for each path, showing only the endpoint path total, required-time, and slack.

-delay *min* | *min_rise* | *min_fall* | *max* | *max_rise* | *max_fall*

Specifies the path type at the endpoint. The default is **max**.

-nworst *paths_per_endpoint*

Specifies the number of paths to report per endpoint. The default value is 1.

-max_paths *max_path_count*

Specifies the number of paths to report per path group. The default value is 1.

-input_pins

Shows input pins in the path report. The default is to show only output pins. This option also shows the delays of the nets connected to these pins.

-nets
Shows nets in the path report. The default is not to show nets. To show the delay for the nets, use the **-input_pins** option.

-transition_time
Shows the net transition time for each driving pin in the path report. The default is not to show the net transition time for each driving pin.

-crosstalk_delta
Shows the delta delay for each input pin in the path report. The default is not to show the delta delay for each input pin.

-capacitance
Indicates that total (lump) capacitance be shown in the path report. The default is not to show capacitance. For each driver pin, the total capacitance driven by the driver is displayed in a column preceding both incremental path delay and transition time (specified with **-transition_time**). When **-nets** is specified, the capacitance is printed on the lines with nets instead of the lines with driver pins.

-attributes
Shows the attributes specified in the **timing_report_attributes** variable. The current set of attributes supported are **dont_touch**, **dont_use**, **map_only**, and **size_only** for cells, and **dont_touch** and **ideal_net** for nets.

-physical
Shows the locations of the pins and the capacitive loads for the pins and nets in the path report. The loads are displayed as a pair of values with the first value being the wire capacitance of the net and the second value being the total capacitance driven by the driver. If the pin location cannot be determined, the cell location is displayed, with the coordinates in microns.

-slack_greater_than greater_slack_limit
Specifies that only those paths with a slack greater than *greater_slack_limit* are to be reported. This option can be combined with **-slack_lesser_than** to report only those paths inside or outside a given slack range.

-slack_lesser_than lesser_slack_limit
Specifies that only those paths with a slack less than *lesser_slack_limit* are to be reported. This option can be combined with **-slack_greater_than** to report only those paths inside or outside a given slack range.

-lesser_path max_path_delay
Selects only those paths with a delay less than *max_path_delay*. Combine this option with the **-greater_path** option to select only those paths inside or outside a given delay range.

-greater_path min_path_delay
Selects only those paths with a delay greater than *min_path_delay*. Combine this option with the **-lesser_path** option to select only those paths inside or outside a given delay range.

-loops
Reports only the timing loops in the design.

-true
Reports the longest (least-slack) true paths in the design. This option can require long runtimes for certain designs that have many false paths. Use the **true_delay_prove_true_backtrack_limit** and **true_delay_prove_false_backtrack_limit** variables to limit the amount of backtracking during the operation of **report_timing -true**. Use the **set_true_delay_case_analysis** command to specify a partial input vector to be considered for **-true** analysis. You cannot combine **-true** with the **-max_paths(>1)**, **-nworst(>1)**, **-lesser_path**, **-greater_path**, **-slack_lesser_than**, **-slack_greater_than**, **-loops**, or **-delay** (path type other than max) options. This option requires a DC Ultra license.

-true_threshold path_delay
Specifies a threshold path delay value, in library time units, to be used by the **-true** option to speed up the searching. This option is only used the **true** option. If you specify this option, **report_timing -true** returns the first path it finds that is greater than or equal to *path_delay*, rather than continuing to search for a longer one. This option requires a DC Ultra license.

-justify
Finds an input vector that sensitizes the reported paths, or reports that the path is false if no input vector is found. Use the **set_true_delay_case_analysis** command to specify a partial input vector to be considered for **-justify** analysis. You cannot use this option with the **-loops** option. This option requires a DC Ultra license.

-enable_preset_clear_arcs
Enables asynchronous timing arcs for this report. By default, asynchronous timing arcs are disabled during all timing verification. This option allows you to see the timing with these arcs enabled. Only the current report is affected.

-significant_digits digits
Specifies the number of digits to the right of the decimal point to report. Allowed values are from 0 through 13. The default is 2. Using this option overrides the value set by the **report_default_significant_digits** variable.

-nosplit
Prevents line-splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-sort_by group | slack
Specifies the order in which the paths are reported. The default **-sort_by** key is **group**. By default, paths are sorted by costing groups. Within each group, the paths are ordered by slack. With **slack**, the paths are ordered by slack only.

-group group_name
Specifies the path group from which timing paths are selected for reporting, based on other specified options for reports. If **-group** is not specified, the reported paths are a subset of paths from all path groups. This option cannot be used with **-loops**.

`-trace_latch_borrow`

This option controls the type of report generated for a path that starts at a transparent latch. If the path startpoint borrows from the previous stage, using this option causes the report to show the entire set of borrowing paths that lead up to the borrowing latch, starting with a nonborrowing path or a noninverting sequential loop. By default, the report shows only the last path in the sequence of borrowing stages. Each stage is reported separately, showing the time borrowed and lent and the endpoints of the stage. The cumulative amount of borrowed time along a sequence of stages is not included in the report. The **-input_pins**, **-nets**, **-transition_time**, **-capacitance**, and **-significant_digits** option apply to every stage in the sequence of borrowing paths, but the remaining options (for example, **-from** and **-true**) apply only to the last stage reported.

`-derate`

Prints timing derate values for each path element. By default, no derate value is printed. When this option is specified, the **-input_pins** and **-nets** options are automatically turned on. Input delay and ideal clock network latency is not derated.

`-scenario scenario_list`

Option `"-scenario all"` has been replaced by `"-scenario scenario_list"` to reports timing for given list of scenarios of a multi-scenario design. please replace "all" setting in existing scripts with "[all_scenarios]" to get the same results as before. Inactive scenarios will be skipped in the report. Each scenario is reported separately, with up to **-max_paths** paths reported for each scenario. If this option is not given, only the current scenario is reported.

`-temperature`

For multivoltage designs, reports the operating condition temperature for each path element.

`-voltage`

For multivoltage designs, reports the operating condition voltage for each path element.

DESCRIPTION

The **report_timing** command provides a report of timing information for the current design. By default, the **report_timing** command reports the single worst setup path in each clock group.

The command options let you specify the number of paths reported, the types of paths reported, and the amount of detail included in the report. You can restrict the scope of paths reported by startpoints, endpoints, and intermediate points by using the **-from**, **-to**, and **-through** options; and by slack or clock group by using the **-slack_lesser_than** and **-group** options.

The timing report starts by showing the primary command settings, operating conditions, path startpoint, path endpoint, path group name, and path timing check type (max for a setup check, min for a hold check, and so on).

A table in the report shows point-by-point accounting of the delays along the path

from the startpoint to the endpoint. The default table has columns labeled Point, Incr, and Path. These columns list the points (cell pins) along the path, the incremental contribution to the delay at each point, and the cumulative delay up to that point, respectively. Hierarchical boundary crossings are listed as well, showing zero incremental delay at each crossing. You can optionally display net delays in the report by using the **-input_pins** option and net names by using the **-nets** option.

The symbols **r** and **f** in the Path column indicate the sense of the signal transition, either rising or falling, at that point in the path.

For a setup check, the path starts with the launch clock edge and ends at the data input of the capture device. The data arrival time shown in the table is the amount of elapsed time from the source of the launch clock edge to the arrival of data at the endpoint, taking into consideration the longest possible delays along the path.

Following this is the accounting for the required arrival time. The data required time shown in the table is the latest allowable arrival time for the data at the path endpoint, taking into account the nominal capture clock edge time, the clock network delay, the clock uncertainty, the least possible delay along the clock path, and the library setup time requirement for the capture device.

The slack value shown at the end of the report is the data required time minus the data arrival time. This represents the amount of time by which the timing constraint is met.

Back-annotations on path elements in the timing path are indicated by a character symbol in the Incr column. If the **-input_pins** option is used, each pin-to-pin delay spans either a net or cell. The symbol shown refers to the dominant annotation on this path element. (Certain annotations dominate others; for example, SDF takes precedence over back-annotated RC parasitics.) Without **-input_pins**, the delay shown may span both a net and a cell. If they have the same dominant annotation, the appropriate symbol is shown; otherwise, the symbol "H" appears to show that a hybrid of annotation types exists on the corresponding path segment.

Symbol	Annotation
-----	-----
H	Hybrid annotation
^	Ideal network latency annotation
*	SDF back-annotation
&	RC network back-annotation
\$	RC pi back-annotation
+	Lumped RC
<none>	Wire-load model or none

You can use multiple **-through** options in a single command to specify paths that traverse multiple points in the design. The following example specifies paths beginning at A1, passing through B1, then through C1, and ending at D1:

```
prompt> report_timing -from A1 -through B1 -through C1 -to D1
```

If more than one object is specified within one **-through** option, the path can pass through any of the objects. The following example specifies paths beginning at A1,

passing through either B1 or B2, then passing through either C1 or C2, and ending at D1:

```
prompt> report_timing -from A1 -through {B1 B2} -through {C1 C2} -to D1
```

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenario** option.

EXAMPLES

The following example shows a timing report using only the default values:

```
prompt> report_timing
```

```
*****
Report : timing
  -path full
  -delay max
  -max_paths 1
Design : led

ARGUMENTS

-include_inherited

Reports the derates on the object, including those that are inherited. The derates reported are the ones used in the delay calculation. The name of the cell or design from which the derate is inherited is shown in the "Inherited" column. When this option is not specified, only user defined values are reported.

object_list

Specifies the list of objects whose derate factors need to be reported. If an object list is not specified, all objects in the current design with user-defined derates are displayed. The objects in the list can be leaf cells, instances, library cells, and designs.

-nosplit

Prevents line-splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-scenario scenario_list

Reports timing derate for given list of scenarios of a multiscenario design. Inactive scenarios will be skipped in the report. Each scenario is reported separately. If this option is not given, only the current scenario is reported.

DESCRIPTION

The **report_timing_derate** command reports derate factors for the design or specified objects. When the **-include_inherited** option is specified, derate factors that are used in delay calculation are reported. The derate factors can be the ones set on the object by user, or inherited from other objects. By default, only user-defined derate factors are reported.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenario** option.

EXAMPLES

The following example reports derates for all of the objects in current design that have user-defined derate factors:

```
prompt> report_timing_derate
```

The next example reports all derates for the *s1* instance.

```
prompt> report_timing_derate s1 -include_inherited
```

SEE ALSO

```
report_timing(2)  
reset_timing_derate(2)  
set_timing_derate(2)
```

report_timing_requirements

Reports timing path requirements (user attributes) and related information.

SYNTAX

```
int report_timing_requirements
[-attributes]
[-ignored]
[-from from_list
 | -rise_from rise_from_list
 | -fall_from fall_from_list]
[-through through_list]
[-rise_through rise_through_list]
[-fall_through fall_through_list]
[-to to_list
 | -rise_to rise_to_list
 | -fall_to fall_to_list]
[-expanded]
[-nosplit]
```

Data Types

from_list	list
rise_from_list	list
fall_from_list	list
through_list	list
rise_through_list	list
fall_through_list	list
to_list	list
rise_to_list	list
fall_to_list	list

ARGUMENTS

-attributes
Lists the path delay attributes set on the design. If used with the **-from** or **-to** option, **-attributes** limits the report to the specified from and to objects. This option reports on attributes set by the **set_multicycle_path**, **set_false_path**, **set_max_delay**, and **set_min_delay** commands.
The **-attributes** option is the default when no other options are specified.
Any **max_time_borrow** attributes on objects are printed.

-ignored
Lists path timing attributes set on the current design that are ignored. For example, a false path may have been specified from port A to port Z1, but there is no timing path between those points. Use **-from** or **-to** to limit the report to certain paths. Ignored attributes on objects are printed, such as **max_time_borrow** on a cell other than a level-sensitive latch.

-from from_list
Specifies a list of clocks, ports, cells, and pins in the current design. The **-from** option limits the report to information that was set with **-from** to a

path-based command, such as **set_multicycle_path**.

-rise_from *rise_from_list*

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Same as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through *through_list*

Specifies a list of ports, cells, and pins in the current design. The **-through** option limits the report to information that was set with **-through** to a path-based command, such as **set_multicycle_path**.

-rise_through *rise_through_list*

Same as the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than once in a single command invocation as with the **-through** option.

-fall_through *fall_through_list*

Same as the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than once in a single command invocation as with the **-through** option.

-to *to_list*

Specifies a list of clocks, ports, cells, and pins in the current design. The **-to** option limits the report to information that was set with **-to** to a path-based command, such as **set_multicycle_path**.

-rise_to *rise_to_list*

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to *fall_to_list*

Same as the **-to** option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-expanded

Expands compressed timing exceptions on the design. Compressed timing exceptions applied on the design are reported as compressed exceptions by the **report_timing_requirements** command. Although every object in the from, to,

and through list gets enumerated, the exception is still a compressed exception. With the **-expanded** switch, these exceptions are expanded so that each of the from, to, and through list references at the most one element. It is considered best practice not to use this switch, since it can create a very large report.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_timing_requirements** command produces a report showing information about timing requirements of the design.

Use the **reset_design** command to remove all timing attributes on the current design. To remove timing attributes from specified paths, use the **reset_path** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example lists all timing attributes set on the design:

```
prompt> report_timing_requirements
*****
Report : timing_requirements
    -attributes
Design : counter
Version: v3.0
Date   : Thu Mar 19 19:28:32 1992
*****
```

From	Through	To	Setup	Hold
RESET	*	*	FALSE	FALSE
*	U1/Z, U5/A	CO	max=4.5	min=2.2
ffa	*	ffb	cycles=2	-

The following example lists all ignored timing attributes set on the design:

```
prompt> report_timing_requirements -ignored
*****
Report : timing_requirements
    -ignored
```

```
Design : counter
Version: v3.0
Date   : Mon Apr 20 19:03:38 1992
*****
```

set_max_time_borrow(2)
set_min_delay(2)
set_multicycle_path(2)
```

report_tlu_plus_files

Reports the files used for TLUPlus extraction.

SYNTAX

```
integer report_tlu_plus_files
[-scenario scenario_list]
```

ARGUMENTS

```
-scenario scenario_list
    Reports tlu plus files for given list of scenarios of a multiscenario design.
    Inactive scenarios will be skipped in the report. Each scenario is reported
    separately. If this option is not given, only the current scenario is
    reported.
```

DESCRIPTION

This command reports the files used for virtual route and post route extraction using TLUPlus.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example runs the **report_tlu_plus_files** command.

```
prompt> report_tlu_plus_files
```

SEE ALSO

```
extract_rc(2)
set_tlu_plus_files(2)
```

report_track

Reports the routing tracks for a specified layer or for all layers.

SYNTAX

```
int report_track
[-layer layer]
[-dir X | Y]
```

Data Types

layer string

ARGUMENTS

-layer *layer*
Specifies the routing layer to use the routing tracks. You can use layer name, layer number, or a collection containing one layer object.
The default is to report the routing tracks on all layers.

-dir X | Y
Specifies the direction how routing tracks are placed. The valid values are **X** and **Y**; specify either. The default is to report routing tracks in both direction.

DESCRIPTION

This command reports a group of routing tracks for the routing layer.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports routing tracks on the floorplan.

```
prompt> report_track
*****
Report track
Design : design

`remove_track(2)`

report_transitive_fanin

Reports logic in the transitive fanin of specified sinks.

SYNTAX

```
int report_transitive_fanin
-to sink_list
[-nosplit]
```

Data Types

sink_list list

ARGUMENTS

-to *sink_list*
Specifies a list of sink pins, ports, or nets in the design. The transitive fanin of each sink in the *sink_list* is reported. If a net is specified, the effect is the same as listing all driver pins on the net. This argument is required.

-nosplit
Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_transitive_fanin** command produces a report showing the transitive fanin of specified sink pins, ports, or nets in the design. A pin is considered to be in the transitive fanin of a sink if there is a timing path through combinational logic from the pin to that sink. The fanin report stops at the clock pins of registers (sequential cells).

Use the **report_timing** command to show path delays in the design. Use the **report_transitive_fanout** command to see the fanout of a pin, port, or net.

If the *current_instance* is set, the report focuses on the fanin within the current instance. The report stops at the boundaries of the current instance, and paths outside the current instance are not reported. The report shows the hierarchical boundary pins on the current instance.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows the transitive fanin of two internal pins in the design:

```
prompt> report_transitive_fanin -to {u5/A u5/B}
```

```
*****
Report : transitive_fanin
Design : counter
Version: v3.1
Date   : Thu 1992
*****
```

The fanin network of sink u5/A is as follows:

Driver Pin	Load Pin	Type	Sense
u2/Z	u5/A	(net arc)	same

Load Pin	Driver Pin	Type	Sense
u2/A	u2/Z	IVA	opposite

Driver Pin	Load Pin	Type	Sense
b	u2/A	(net arc)	opposite

The fanin network of sink u5/B is as follows:

Driver Pin	Load Pin	Type	Sense
c	u5/B	(net arc)	same

SEE ALSO

[current_instance\(2\)](#)
[report_clock\(2\)](#)
[report_timing\(2\)](#)
[report_transitive_fanout\(2\)](#)

report_transitive_fanout

Reports logic in the transitive fanout of specified sources.

SYNTAX

```
int report_transitive_fanout
-clock_tree | -from source_list
[-nosplit]
```

Data Types

source_list list

ARGUMENTS

-clock_tree
Indicates that all clock source pins and/or ports in the design are to be used as the list of sources. Clock sources are specified using the **create_clock** command. If there are no clocks, or if the clocks do not have sources, the report is empty. Use the **report_clock** command to list the sources for all clocks in the design. The **-clock_tree** option is a special form of the report that displays the clock trees (or "networks") in the design.
Either the **-clock_tree** or the **-from** option must be specified. The options are mutually exclusive, so specify only one.

-from source_list
Specifies a list of source pins, ports, and/or nets in the design. The transitive fanout of each source in the *source_list* is reported. If a net is specified, the effect is the same as listing all load pins on the net.
Either the **-clock_tree** or the **-from** option must be specified. The options are mutually exclusive, so specify only one.

-nosplit
Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_transitive_fanout** command produces a report showing the transitive fanout of specified source pins or ports in the design. A pin is considered to be in the transitive fanout of a source if there is a timing path through combinational logic from the source to that pin. The fanout report stops at the inputs to registers (sequential cells). The source pins or ports are specified with either **-clock_tree** or **-from source_list**.

Use the **report_timing** command to show path delays in the design. Use the **report_transitive_fanin** command to see the fanin of a pin, port, or net.

If the *current_instance* is set, the report focuses on the fanout within the current instance. The report stops at the boundaries of the current instance, and does not report paths outside the current instance. The report also shows the hierarchical boundary pins on the current instance.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example lists the transitive fanout for all clock sources in the design:

```
prompt> report_transitive_fanout -clock_tree

*****
Report : transitive_fanout
    -clock_tree
Design : counter
Version: v3.0
Date   : Thu 1992
*****
```

The fanout network of source CLK is as follows:

Driver Pin	Load Pin	Type	Sense
CLK	ffd/CP	(net arc)	same
CLK	ffc/CP	(net arc)	same
CLK	ffb/CP	(net arc)	same
CLK	ffa/CP	(net arc)	same

The following example shows the transitive fanout of two internal pins in the design:

```
prompt> report_transitive_fanout -from {ffa/Q ffb/Q}

*****
Report : transitive_fanout
Design : counter
Version: v3.0
Date   : Thu 1992
*****
```

The fanout network of source ffa/Q is as follows:

Driver Pin	Load Pin	Type	Sense
ffa/Q	QA/A	(net arc)	same

Load Pin	Driver Pin	Type	Sense
----------	------------	------	-------

QA/A	QA/Z	IV	opposite
Driver Pin	Load Pin	Type	Sense
-----	-----	-----	-----
QA/Z	QA	(net arc)	opposite

The fanout network of source ffb/Q is as follows:

Driver Pin	Load Pin	Type	Sense
-----	-----	-----	-----
ffb/Q	QB/A	(net arc)	same
Load Pin	Driver Pin	Type	Sense
-----	-----	-----	-----
QB/A	QB/Z	IV	opposite
Driver Pin	Load Pin	Type	Sense
-----	-----	-----	-----
QB/Z	QB	(net arc)	opposite

```

report_units

Reports the units used for resistance, capacitance, timing, leakage power, current, and voltage in the flow. The units must be consistant with the main library units.

SYNTAX

```
string report_units
```

ARGUMENTS

The **report_units** command has no arguments.

DESCRIPTION

The **report_units** command displays the units used by the current design. To generate the report the design should be loaded and linked to a library. The units are always reported in reference to the MKS units like farad, amp, ohm, second, volt and watt.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the report_units output.

```
*****
Report : units
Design : labf.mw
Version: Z-2007.03-ICC

Date   : Tue Aug 22 10:32:44 2006
*****
Units
-----
Time_unit      : 1e-09 Second(nS)
Capacitive_load_unit : 1e-12 Farad(pF)
Resistance_unit    : 1000 Ohm(kohm)
Voltage_unit     : 1 Volt
Power_unit       : 1e-06 Watt(uW)
Current_unit     : 1 Amp
```

SEE ALSO

`set_units(2)`

report_voltage_area

Reports the voltage areas in the design.

SYNTAX

```
int report_voltage_area  
-all | patterns
```

Data Types

patterns list

ARGUMENTS

-all

Specifies that all voltage areas in the design must be reported. The voltage areas are created by using the **create_voltage_area** command for the hierarchical blocks.

patterns

Specifies the voltage areas to be reported. The patterns can be a collection handle of voltages or names of patterns. You can use the **get_voltage_areas** command to specify voltage areas to be reported.

DESCRIPTION

This command generates reports the user-specified voltage area constraints in the design, as specified by the **create_voltage_area** command. If you use the **-all** option, all voltage areas in the design, created by the **create_voltage_area** command are reported.

The report generated includes voltage area name, hierarchical blocks associated with voltage area, voltage area geometry, area of the voltage area, and utilization for the voltage area. The area of the voltage area is specified in microns.

Voltage areas can physically be completely nested: one voltage area lies completely inside another voltage area. When considering the area or utilization of the outside voltage area, the area of the inner voltage area is excluded.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the voltage area *val*.

```
prompt> report_voltage_area val  
*****
```

```
Voltage area name val
Block(s) :PPL_LBUS_CORE
Voltage area geometry : {19.87 29.86 576.47 1148.89}
Voltage area region Area : 622854.88
Voltage area Utilization : 0.66
Voltage Area Guard-band (X, Y) : (1, 1)

report_vt_filler_rule

Writes out multiple threshold voltage filler cell insertion rules.

SYNTAX

```
status report_vt_filler_rule
      -threshold_voltage vt_type_1_vt_type_2
```

ARGUMENTS

```
-threshold_voltage vt_type_1_vt_type_2
      Specifies threshold voltage types of the rule to be writes out
```

DESCRIPTION

Use this command to report multiple threshold voltage filler rules of the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example will print out rules for threshold voltage "vtType1" and "vtType2".

```
prompt> report_vt_filler_rule -threshold_voltage {vtType1 vtType2}
```

The following example will print out all threshold voltage rules for current design

```
prompt> report_vt_filler_rule
```

Below is an exmaple of the output. The current design library is "design", with 2 reference libraries MVT_LIB_2 and LVT_LIB_2. No vt filler rule defined for cells in "design". one cell L1SUBCON1 in library MVT_LIB_2 is defined as a filler between threshold voltage vtType1 and vtType1. Two cells L2SUBCON1 and L2SUBCON2 in library LVT_LIB_2 are defined as fillers between vtType2 and vtType2. ;; VT fillers in library MVT_LIB_2 L1SUBCON1: vtType1vtType1Filler

```
;; VT fillers in library LVT_LIB_2 L2SUBCON1: vtType2vtType2Filler L2SUBCON2:
vtType2vtType2Filler
```

```
;; VT fillers in library design
```

SEE ALSO

```

```

report_write_stream_options

Reports stream out options for the **write_stream** command.

SYNTAX

```
status report_write_stream_options  
[-default]
```

ARGUMENTS

-default
Report the default value of write_stream options. If this option is not specified, current option values are reported.

DESCRIPTION

Command **report_write_stream_options** is used to examine the options which are set by **set_write_stream_options** command. If an option is not specified, the default value will be reported. Both **set_write_stream_options** and **report_write_stream_options** serve **write_stream**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the options for write_stream.

```
prompt> set_write_stream_options  
-child_depth 1  
-output_filling {gap}  
prompt> report_write_stream_options
```

SEE ALSO

```
set_write_stream_options(2)  
write_stream(2)
```

report_xtalk_route_options

Reports the settings of the global route and track assignment crosstalk options.

SYNTAX

```
status report_xtalk_route_options
[-default]
```

ARGUMENTS

```
-default
    Reports default options
```

DESCRIPTION

This command reports the settings of global route and trackAssignment xtalk options that have been set by the **set_xtalk_route_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the use of the command.

```
prompt> report_xtalk_route_options
```

SEE ALSO

```
set_xtalk_route_options(2)
```

report_zrt_net_properties

Reports the property settings for a net.

SYNTAX

```
status report_zrt_net_properties
      -net net_name
```

Data Types

net_name string

ARGUMENTS

```
-net net_name
      Specifies the net name from which to get the property settings. This argument
      is required.
```

DESCRIPTION

The **report_zrt_net_properties** command returns a values of all properties of the specified net.

EXAMPLES

The following example reports the property settings for a net:

```
prompt> report_zrt_net_properties -net "n1"
```

SEE ALSO

```
set_zrt_net_properties(2)
get_zrt_net_properties(2)
```

reset_clock_tree_optimization_options

Resets options used by clock tree optimization.

SYNTAX

```
status reset_clock_tree_optimization_options
[-clock_trees clock_name_or_collection]
[-enable_multicorner_optimization]
[-gate_sizing]
[-gate_relocation]
[-preserve_levels]
[-area_recovery]
[-all]
[-balance_rc]
[-relax_insertion_delay]
[-corner_target_skew]
```

ARGUMENTS

-clock_trees *clock_name_or_collection*

Specifies a set of clocks to be processed. Only clock names defined through `create_clock` or `create_generated_clock` are accepted. If there is a list of clock names, the options then apply to those clocks only. By default, the options apply for all the clocks.

-enable_multicorner_optimization

Reset the type of Multi-corner optimization to default. Multi-corner optimization default is none. This option can not be specified together with `"-clock_trees clock_name_or_collection"`. In addition to enabling multi-corner optimization option, user should also set min libraries using `set_min_library`; then we do 2-corner optimization. When `real_corners` is given, tool will perform optimization based on libraries provided. In the case of `virtual_corners`, tool will create multiple corners and do optimization.

-gate_sizing

Reset gate sizing to default. By default, `gate_sizing` is **true**. The gates in question are the user instantiated gates and buffers only and not introduced cells during `compile_clock_tree` or `optimize_clock_tree`; `Compile_clock_tree` or `optimize_clock_tree` introduced cells can always be sized, with the exception of boundary cells. User gates, for example, are those that are introduced during prior to `compile_clock_tree`, or user may have put them for some purpose.

-gate_relocation

Reset gate relocation to default. By default, `gate_relocation` is **true**. The gates in question are the user instantiated gates and buffers only and not introduced cells during `compile_clock_tree` or `optimize_clock_tree`; `Compile_clock_tree` or `optimize_clock_tree` introduced cells can always be relocated. User gates, for example, are those that are introduced prior to `compile_clock_tree`, or user may have put them for some purpose.

```

-preserve_levels
    Reset preserve_levels to default. By default, preserve_levels is false. If set to true, then the number of levels will be preserved. This option is combining delay insertion and delay removal options. The target_early_delay, if specified with set_clock_tree_options, will override preserve_levels only at the root of the clock.

-area_recovery
    Reset area_recovery to default. By default, area_recovery is true.

-all
    Reset all of above options to default.

```

DESCRIPTION

This command is the UI resetting options for clock tree optimization in ICC. Before command optimize_clock_tree or clock_opt, user can use this command to reset options to specific clocks if -clock_trees is given, or reset options to the design which will be applied to all clocks that do not have the per clock option.

By disabling multi-corner optimization, the tool will not perform multi-corner optimization. User can use this command to enable sizing or relocation to cells that were introduced prior to compile_clock_tree. Area recovery is a tool to reduce clock buffer area, significantly in some cases. User can turn it on through this command.

This command only resets options to default for optimize_clock_tree. In clock_opt, compile_clock_tree and optimize_clock_tree are called. This reset_clock_tree_optimization_options only affect optimize_clock_tree part of clock_opt.

Options -gate_sizing, -gate_relocation are both under set_clock_tree_options and set_clock_tree_optimization_options. If they are under set_clock_tree_optimization_options, they control optimize_clock_tree; if under set_clock_tree_options, they control optimization during compile_clock_tree. Under set_clock_tree_options, there are -buffer_sizing/-buffer_relocation/-delay_insertion. They also only control compile_clock_tree.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example disables gate_sizing to clock PCI_CLK. Then reset gate_sizing to default (enable) for clock PCI_CLK.

```

prompt> set_clock_tree_optimization_options -clock_trees [get_clock PCI_CLK]\
-gate_sizing false
1
prompt> reset_clock_tree_optimization_options -clock_trees
[get_clock PCI_CLK] -gate_sizing

```

1

This example sets the multicorner optimization type to real_corners to all clocks. Then reset multicorner optimization to default (none) for all clocks.

```
prompt> set_clock_tree_optimization_options -  
enable_multicorner_optimization real_corners  
1  
prompt> reset_clock_tree_optimization_options -enable_multicorner_optimization  
1
```

reset_clock_tree_options

Removes clock tree options which are set by user using **set_clock_tree_options** command.

SYNTAX

```
void reset_clock_tree_options
[-root pin_col_spec]
[-buffer_relocation]
[-buffer_sizing]
[-delay_insertion]
[-gate_relocation]
[-gate_sizing]
[-layer_list]
[-max_buffer_levels]
[-max_capacitance]
[-max_fanout]
[-max_transition]
[-max_rc_delay_constraint]
[-max_rc_scale_factor]
[-routing_rule]
[-target_early_delay]
[-target_skew]
[-use_default_routing_for_sinks]
[-top_mode]
[-logic_level_balance]
[-config_file_read]
[-config_file_write]
[-all]
[-global]
[-ocv_clustering]
```

Data Types

pin_col_spec list

ARGUMENTS

-root *pin_col_spec*

Removes the specified user-set options for only those clock trees whose root pins are listed in *pin_col_spec*. Each element of *pin_col_spec* is the name of the source (a top-level design input port or a library cell instance pin) of each clock tree.

If you use the **reset_clock_tree_options** command without the **-root** option, the command is applied to all currently-defined clock trees in the design.

-buffer_relocation

Removes the buffer relocation switch set by user in **set_clock_tree_options** command and use "true" as default. This switch is for clock tree optimization. This option is clock specific among all clock trees.

-buffer_sizing
Removes the buffer sizing switch set by user in **set_clock_tree_options** command and use "true" as default. This switch is for clock tree optimiztion. This option is clock specific among all clock trees.

-delay_insertion
Removes the delay insertion switch set by user in **set_clock_tree_options** command and use "false" as default. This switch is for clock tree optimiztion. This option is clock specific among all clock trees.

-gate_relocation
Removes the gate relocation switch set by user in **set_clock_tree_options** command and use "true" as default. This switch is for clock tree optimiztion. This option is clock specific among all clock trees.

-gate_sizing
Removes the gate sizing switch set by user in **set_clock_tree_options** command and use "false" as default. This switch is for clock tree optimiztion. This option is clock specific among all clock trees.

-layer_list
Removes the list of layers specified by user in **set_clock_tree_options** command and use all available layers as default. The list of layers can be used during routing of clock nets. This option is clock specific among all clock trees.

-max_buffer_levels
Removes the maximum number of levels specified by user in **set_clock_tree_options** command and use "20" as default. The maximum number of levels can be used for buffering a clock net. This option is clock specific among all clock trees.

-max_capacitance
Removes the maximum capacitance design rule checking (DRC) constraint set by user in **set_clock_tree_options** command and use "0.6" as default. This constraint is for the buffers and inverters used while compiling the specified clock tree. This option is clock specific among all clock trees.

-max_fanout
Removes the maximum fanout design rule checking (DRC) constraint set by user in **set_clock_tree_options** command and use "2000" as default. This constraint is for the buffers and inverters used while compiling the specified clock tree. This option is clock specific among all clock trees.

-max_transition
Removes the maximum transition design rule checking (DRC) constraint set by user in **set_clock_tree_options** command and use "0.5" as default. This constraint is for the buffers and inverters used while compiling the specified clock tree. This option is clock specific among all clock trees.

-max_rc_delay_constraint
Removes the maximum RC delay constraint set by user in **set_clock_tree_options** command and disables this constraint as default. This constraint is for the delay from a driver pin to each receiver pin. This option is clock specific among all clock trees.

-max_rc_scale_factor
Removes the scale factor associated with the maximum RC delay constraint set by user in **set_clock_tree_options** command and disables this constraint as default. This constraint is for the delay from a driver pin to each receiver pin. This option is clock specific among all clock trees.

-routing_rule
Removes the nondefault routing rule specified by user in **set_clock_tree_options** command and use default routing rule. This option is clock specific among all clock trees.

-target_early_delay
Removes the minimum insertion delay constraint specified by user in **set_clock_tree_options** command and use "0" as default. This option is clock specific among all clock trees.

-target_skew
Removes the maximum skew soft constraint specified by user in **set_clock_tree_options** command and use "0" as default. This option is clock specific among all clock trees.

-use_default_routing_for_sinks
Removes N, which is set by user in **set_clock_tree_options** command, and use "0" as default, supposing that the default routing rule is used on the nets driving sinks at the bottom N levels of the clock tree. This option is global among all clock trees.

-top_mode
Removes the new top mode algorithm switch specified by user in **set_clock_tree_options** command and use "false" as default. The new algorithm is for building the clock tree after clustering. This option is global among all clock trees.

-logic_level_balance
Removes the balanced logic level switch specified by user in **set_clock_tree_options** command and use "false" as default. This switch is used during building the clock tree. This option is global among all clock trees.

-config_file_read
Removes the specified configuration file name set by user in **set_clock_tree_options** command and use "None" as default. This option is global among all clock trees.

-config_file_write
Removes the specified configuration dump file name set by user in **set_clock_tree_options** command and use "None" as default. This option is global among all clock trees.

-all
Removes all the clock specific options set by user in **set_clock_tree_options** command. -all is equivalent to "-buffer_relocation -buffer_sizing -delay_insertion -gate_relocation -gate_sizing -layer_list -max_buffer_levers -max_capacitance -max_fanout -max_transition -routing_rule -target_early_delay -target_skew".

```
-global
    Removes all the global options set by user in set_clock_tree_options command.
    -global is equivalent to "-use_default_routing_for_sinks -top_mode -
    logic_level_balance -config_file_read -config_file_write".

-ocv_clustering
    Removes the OCV(On Chip Variation)-aware register clustering switch specified
    by user in set_clock_tree_options command and use "false" as default. The
    OCV-aware register clustering is for capturing timing-critical endpoints, to
    improve clock path sharing between the relatively more timing-critical
    register pairs.
```

DESCRIPTION

This command deletes the database entry for the clock tree object predefined by the **set_clock_tree_options** command. If no other options except for -root are used, nothing will change to the user set options.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This example creates and modifies a new clock tree structure named *CLK1*. The library units for the technology are in pico-seconds and femto-farads. It creates a clock tree with a source pin named *U1/Z* and then removes it.

```
prompt> set_clock_tree_options -root \
[get_pins U1/Z] -buffer_relocation false -gate_relocation false
prompt> reset_clock_tree_options -root [get_pins U1/Z] \
-buffer_relocation -gate_relocationfp
```

SEE ALSO

`set_clock_tree_options(2)`

reset_clock_tree_references

Removes previously defined references from a clock tree.

SYNTAX

```
status reset_clock_tree_references
[-references pin_collection]
```

ARGUMENTS

-references *pin_collection*

Specifies a list of references the command is to remove from the list of buffers and inverters local to the specific clock tree (if the -clock_trees option has also been provided) or from the global list of references available to all clock trees of the design. If you do not provide the -references option, the command will remove the contents of the entire buffer list and inverter list.

DESCRIPTION

Use this command to remove chosen references from clock trees you defined previously.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

SEE ALSO

```
compile_clock_tree(2)
set_clock_tree_options(2)
set_clock_tree_references(2)
```

reset_cts_batch_mode

Disables clock tree synthesis batch mode.

SYNTAX

```
status reset_cts_batch_mode
```

ARGUMENTS

None

DESCRIPTION

To reduce runtime in script that call CTS commands many times, in some cases, one clock at a time, the set command turns on the batch mode. It skips CTS pre and post process whenever it can. For example, if 3 compile_clock_tree commands are called, the first call will run the CTS pre-process, but skipped the post process. The second and the third calls will skip both pre and post process. The following command, like reset_cts_batch_mode, save_mw_cel or other trigger commands will make up the CTS post process.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
set_cts_batch_mode  
compile_clock_tree -clock_trees clk1  
compile_clock_tree -clock_trees clk2  
  
report_cts_batch_mode  
optimize_clock_tree  
balance_inter_clcok_delay  
reset_cts_batch_mode
```

SEE ALSO

```
set_cts_batch_mode(2)  
report_cts_batch_mode(2)
```

reset_design

Removes from the current design all user-specified objects and attributes, except those defined using set_attribute.

SYNTAX

```
status reset_design
```

ARGUMENTS

The **reset_design** command has no arguments.

DESCRIPTION

The **reset_design** command removes from the current design all user-specified clocks, path groups, and attributes, except those defined using the **set_attribute** command. This command returns zero if there is no current design.

WARNING: Executing the **reset_design** has extremely wide-ranging consequences. This command removes all user-specified attributes on the design, with a result that is often equivalent to starting the design process from the beginning. If you want to reset only a few attributes, consider using the **remove_attribute** command. Alternatively, you may be able to remove selected attributes using the commands that set them. Many attribute-setting commands, such as **set_jtag_port**, have **-default** options that remove from the current design all attributes previously set by that command. Refer to the appropriate man page to determine whether a specific **set_*** command has the **-default** option.

An often unexpected side effect is that **reset_design** can change the values of some dc_shell variables. For example, if a dc_shell variable contains one or more instance-specific objects (that is, nets, cells or pins below the top level of the design), then when **reset_design** deletes the objects, they are also removed from the dc_shell variable. Thus a variable that contains instance-specific objects no longer contains them after **reset_design** is executed.

For more information on this side effect, and a suggested workaround, refer to the EXAMPLES section.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example resets the current design:

```
prompt> reset_design
Resetting current design 'test'
```

The following example illustrates how the **reset_design** command can change the values of dc_shell variables:

```
prompt> a = [get_cells I_2/U70*]
{"I_2/U709", "I_2/U708", "I_2/U707", "I_2/U706"}

prompt> reset_design
Resetting current design 'TOP'
1

prompt> list a
a = {}
1
```

The following example shows a workaround to the side effect that the **reset_design** command may change the values of dc_shell variables. The **string** variables are not affected by **reset_design**, so to preserve the **object_list** variable, you can save it as a string variable before executing **reset_design**. Then, after executing **reset_design**, you can restore the contents of the original **object_list** variable using the appropriate **get_*** command and the string variable.

```
prompt> list_var = [get_cells I_2/U70*]
{"I_2/U709", "I_2/U708", "I_2/U707", "I_2/U706"}
(NOTE: Variable list_var is a list of design objects.)

prompt> string_var = ""
Warning: Defining new variable 'string_var'. (EQN-10)
"""

(NOTE: Assigning an empty string to a new variable
assures that it is a string variable.)

prompt> string_var = list_var
"{I_2/U709, I_2/U708, I_2/U707, I_2/U706}"
(NOTE: string_var now contains the names of all the
design objects in list_var.)

prompt> reset_design
Resetting current design 'TOP'
1

prompt> list list_var
list_var = {}
1

prompt> list string_var
string_var = "{I_2/U709, I_2/U708, I_2/U707, I_2/U706}"
1
(NOTE: string_var has not been changed by the
reset_design command.)

prompt> list_var = string_var
{"I_2/U709", "I_2/U708", "I_2/U707", "I_2/U706"}
(NOTE: list_var now contains a list of strings,
```

each of which is the name of one of the design
objects previously stored in list_var.)

```
prompt> list_var = [get_cells list_var]
{ "I_2/U709", "I_2/U708", "I_2/U707", "I_2/U706" }
(NOTE: list_var is now restored to the value it had before
the execution of reset_design; that is, a list
of design objects.)
```

SEE ALSO

current_design(2)
remove_attribute(2)
remove_clock(2)
reset_path(2)

reset_fp_clock_plan_options

Removes clock planning options which are set by user using **set_fp_clock_plan_options** command.

SYNTAX

```
status reset_fp_clock_plan_options
[-output_directory]
[-no_feeds_plan_group]
[-clock_nets]
[-anchor_cell]
[-route_mode]
[-keep_block_tree]
[-all]
```

ARGUMENTS

```
-output_directory
    Reset the directory specified by user to write log files. Restore the output
    directory to default value "cp_output".

-no_feeds_plan_group
    Removes the list of plan groups specified by user in which feedthroughs are
    not allowed. By default, feedthroughs are allowed in all plan groups.

-clock_nets
    Removes the list of clock nets specified by user on which clock planning will
    be performed. By default, all clock nets will be processed in clock planning.

-anchor_cell
    Removes the list of lib cell specified by user to be used as anchor cell
    during clock planning. However, user has to specify at least one lib cell to
    perform clock planning.

-route_mode
    Reset the route mode to default value "none", with which clock planning
    performs no interface nets routing.

-keep_block_tree
    Reset the switch value to default "false", so that block level clock tree
    will be removed when clock planning finishes.

-all
    Removes all clock planning option set by user in set_fp_clock_plan_options.
    -all is equivalent to "-output_directory -no_feed_through_plan_groups -
    -clock_nets -anchor_cell -route_mode -is_block_tree_kept"
```

DESCRIPTION

This command removes/resets the database entry for the clock planning options define by user in **set_fp_clock_plan_options** command.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLE

The following example resets all clock planning options.

```
prompt> reset_fp_clock_plan_options -all
```

SEE ALSO

```
set_fp_clock_plan_options(2)
report_fp_clock_plan_options(2)
compile_fp_clock_plan(2)
```

reset_latency_adjustment_options

Resets the options for I/O latency adjustment, defined by using the **set_latency_adjustment_options** command.

SYNTAX

```
status reset_latency_adjustment_options
[-latency]
[-exclude_clock]
[-from_clock]
```

DESCRIPTION

This command resets the I/O latency adjustment options previously set by using the **set_latency_adjustment_options** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example resets the I/O latency adjustment options.

```
prompt> reset_latency_adjustment_options
```

SEE ALSO

set_latency_adjustment_options(2)

reset_mode

Resets the modes of the specified instances.

SYNTAX

```
int reset_mode  
[instance_list]
```

Data Types

instance_list list

ARGUMENTS

instance_list

Specifies a list of instances for which modes are to be reset. If using DCL, all modes except for the default are disabled. If using .lib, all modes of these instances are enabled. No error occurs if you specify to reset the modes on a cell that has no modes.

DESCRIPTION

The **reset_mode** command resets the modes of the specified instances. If no instances are specified, all instances have their modes reset. If using DCL, all modes except for the default are disabled. If using .lib, all modes of these instances are enabled. This is the default behavior when no modes are specified with command **set_mode**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example resets the modes of all instances whose name matches the description RAM*. You can use the command **report_mode** to report the active mode of each instance that have modes. Before executing **reset_mode**, instance Uram1/core was only in read mode, and instance Uram2/core was only in write mode. After executing **reset_mode**, the read and write modes are active for both instances, as shown by the **report_mode** command.

```
prompt> report_mode Uram*
```

```
*****  
Report : mode  
Design : top_design  
*****
```

Cell	Mode (Group)	Status
reset_mode 2000		

Uram1/core(RAM2_core)	read(rw) write(rw)	ENABLED disabled
Uram2/core(RAM2_core)	read(rw) write(rw)	disabled ENABLED

```
prompt> reset_mode RAM*
prompt> report_mode RAM*
```

```
*****
Report : mode
Design : top_design
*****
```

Cell	Mode (Group)	Status
Uram1/core(RAM2_core)	read(rw) write(rw)	ENABLED ENABLED
Uram2/core(RAM2_core)	read(rw) write(rw)	ENABLED ENABLED

SEE ALSO

`report_mode(2)`
`set_mode(2)`

reset_path

Resets specified paths to single cycle timing.

SYNTAX

```
int reset_path
[-setup | -hold]
[-rise | -fall]
[-from from_list
 | -rise_from rise_from_list
 | -fall_from fall_from_list]
[-through through_list]
[-rise_through rise_through_list]
[-fall_through fall_through_list]
[-to to_list
 | -rise_to rise_to_list
 | -fall_to fall_to_list]
```

Data Types

<i>from_list</i>	list
<i>rise_from_list</i>	list
<i>fall_from_list</i>	list
<i>through_list</i>	list
<i>rise_through_list</i>	list
<i>fall_through_list</i>	list
<i>to_list</i>	list
<i>rise_to_list</i>	list
<i>fall_to_list</i>	list

ARGUMENTS

-setup
Specifies that the setup checking (maximum delay) is reset to single cycle behavior.

-hold
Specifies that the hold checking (minimum delay) is reset to single cycle behavior.

-rise
Specifies that the rising path delays are reset to single cycle behavior. The default is that both rising and falling delays are affected.

-fall
Specifies that falling path delays are set to single cycle behavior. The default is that both rising and falling delays are affected.

-from *from_list*
Specifies names of clocks, pins, or cells to use to find path startpoints. If a specified object is a clock, all flip-flops, latches, and primary inputs related to that clock are used as path startpoints.

-rise_from *rise_from_list*

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Same as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through *through_list*

A list of path throughpoints (port, pin, or leaf cell names) of the current design. The **reset_path** applies only to paths that pass through one of the points in the *through_list*. If more than one object is included, the objects must be enclosed either in quotes or in '{}' braces. If you specify the **-through** option multiple times, the **reset_path** applies to paths that pass through a member of each *through_list* in the order the lists were given. In other words, the path must first pass through a member of the first *through_list*, then through a member of the second list, and so on for every through list specified. If you use the **-through** option in combination with the **-from** or **-to** options, the **reset_path** applies only if the **-from** or **-to** conditions are satisfied and the **-through** conditions are satisfied.

-rise_through *rise_through_list*

Same as the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than once in a single command invocation as with the **-through** option.

-fall_through *fall_through_list*

Same as the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than once in a single command invocation as with the **-through** option.

-to *to_list*

Specifies names of clocks, pins, or cells to use to find path endpoints. If a specified object is a clock, all flip-flops, latches, and primary outputs related to that clock are used as path endpoints.

-rise_to *rise_to_list*

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to *fall_to_list*

Same as the **-to** option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock

path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

DESCRIPTION

Specifies that designated timing paths in the current design are restored to the default single cycle behavior. **reset_path** is used to undo the effect of **set_multicycle_path**, **set_false_path**, **set_max_delay**, and **set_min_delay**. Remove the attributes set by those commands with **reset_path**. Note that a general **reset_path** command removes the effect of matching general or specific point-to-point exception commands.

If you don't specify **-setup** or **-hold**, both are restored to the default behavior. The default is a setup relation of one cycle and a hold relation of zero cycles. A hold value of zero means that hold is checked one active edge before the setup data at the destination register.

If you specify **-setup**, only setup (maximum delay) checking is reset to the default behavior. If you specify **-hold**, only hold (minimum delay) checking is reset to the default behavior.

There is separate setup and hold information for rise and fall. In most cases, these are reset together. The **-rise** or **-fall** options are used to reset only one or the other.

To disable setup or hold calculations for paths, use **set_false_path**.

To see the nondefault path requirements on the design, use **report_timing_requirements**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example resets the timing relation between ff1/CP and ff2/D to the default single cycle.

```
prompt> reset_path -from {ff1/CP} -to {ff2/D}
```

This example resets the rising delay to single cycle for all paths ending at latch2d.

```
prompt> reset_path -rise -to {latch2d}
```

This example shows how a specific and general point-to-point exception is set, then removed.

```
prompt> set_false_path 2 -from A -to Z
prompt> set_max_delay 15 -to Z
prompt> reset_path -to Z /* removes all exceptions to Z */
```

set_multicycle_path(2)

reset_split_clock_gates_options

Specifies to reset the options of **split_clock_gates** to the default settings. The set option command is **set_split_clock_gates_options**.

SYNTAX

```
status reset_split_clock_gates_options
```

ARGUMENTS

The **reset_split_clock_gates_options** command has no arguments.

DESCRIPTION

This command resets the options of **split_clock_gates** to the default settings. The default values are:

```
f -honor_dont_touch false  
f -honor_size_only false  
f -slack_margin 0.0
```

SEE ALSO

```
split_clock_gates(2)  
set_split_clock_gates_options(2)  
report_split_clock_gates_options(2)
```

reset_switching_activity

Removes the toggle rate and static probability attributes, or the maximum toggle rate attribute, from nets, pins, cells, and ports of the current design.

SYNTAX

```
integer reset_switching_activity
       -switching_activity | -max_toggle_rate | -all
       [-verbose]
       [object_list]
```

Data Types

object_list list

ARGUMENTS

-switching_activity | -max_toggle_rate | -all

Specifies the attributes to remove from annotated design objects. The **-switching_activity** option (the default) removes only the toggle rate and static probability attributes. The **-max_toggle_rate** option removes only the maximum toggle rate attribute. Specifying **-all** removes all 3 attributes.

-verbose

Prints more information messages than are printed by default.

object_list

Specifies the objects from which to remove the specified attributes. By default, the attributes are removed from all annotated nets, pins, cells, and ports in the current design.

DESCRIPTION

The command enables you to remove the toggle rate, static probability, and maximum toggle rate attributes throughout the entire design. Executing the **reset_switching_activity** command without any arguments removes the toggle rate and static probability attributes.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes all toggle rate and static probability attributes from the *TOP_MULT* design:

```
prompt> current_design TOP_MULT
```

```
prompt> reset_switching_activity
```

The following example removes all maximum toggle rate attributes from the *TOP_MULT* design:

```
prompt> current_design TOP_MULT
prompt> reset_switching_activity -max_toggle_rate -verbose
```

The following example removes all 3 switching activity attributes from the entire design:

```
prompt> current_design TOP_MULT
prompt> reset_switching_activity -all -verbose
```

SEE ALSO

```
read_saif(2)
set_switching_activity(2)
```

reset_timing_derate

Removes all derate factors set on the current design or libraries.

SYNTAX

string **reset_timing_derate**

ARGUMENTS

The **reset_timing_derate** command has no arguments.

DESCRIPTION

The **reset_timing_derate** command removes all timing derates from the current design or libraries. Once the command is run, the result is the same as if timing derates were never set.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes derates for all of the objects in the current design or libraries.

```
prompt> reset_timing_derate
```

SEE ALSO

```
set_timing_derate(2)
report_timing_derate(2)
report_timing(2)
```

reset_upf

Removes all UPF constraints and UPF data-dependent constraints from the current design. This command is supported only in UPF mode.

SYNTAX

```
status reset_upf
```

ARGUMENTS

The **reset_upf** command has no arguments.

DESCRIPTION

The **reset_upf** command is used to clean up all UPF constraints in the current design. This command returns a 1 if successful and returns a 0 otherwise.

The **reset_upf** command also removes UPF data-dependent constraints, which include the following commands:

```
set_voltage  
set_related_supply_net  
set_always_on_strategy
```

After **reset_upf** is executed and new UPF constraints are reloaded using the **load_upf** command, run the above 3 commands again with respect to the new UPF constraints.

Warning: Executing **reset_upf** has extremely wide-ranging consequences. This command removes all UPF constraints in the current design, with a result that is often equivalent to starting the UPF flow. This command removes UPF constraints without touching the netlist. The command does not check if the netlist has been processed by prior UPF constraints. All commands that might change the netlist after the **load_upf** command will not be backed out by the **reset_upf** command. Remember to verify that the UPF constraints are consistent.

You can choose to use **remove_power_domain**, **remove_supply_net**, and so on to remove a single UPF object.

EXAMPLES

The following example shows a typical use of the *reset_upf* command:

```
prompt> load_upf upf_file1  
prompt> reset_upf  
prompt> load_upf upf_file2  
1
```

The following example shows one of the risks of using the **reset_upf** command. After running the **reset_upf** command, the power domain is removed along with the

relationship of the power domain with its related voltage area. So even after reloading the UPF file, you cannot get related power domain information on those voltage areas. In this case, remove the related voltage areas and recreate them with the power domain.

```
prompt> get_voltage_area VA1
VA1
prompt> get_power_domain VA1
VA1
prompt> reset_upf
prompt> load_upf upf_file
prompt> set_fp_rail_voltage_area_constraints \
      -voltage_area VA1 -voltage_supply 1.08
Error: Cannot get supply net from UPF in power domain VA1. (PNA-052)
```

SEE ALSO

```
load_upf(2)
save_upf(2)
remove_power_domain(2)
remove_power_switch(2)
remove_supply_net(2)
remove_supply_port(2)
```

resize_objects

Resizes one or more objects.

SYNTAX

```
status resize_objects
{-bbox bounding_box
 | -delta offset
 | -scale scale_factor
 | -width object_width
 | -height object_height
 | -utilization util_factor
 | -aspect aspect
 | -area area_name}
[-keep_placement]
[-keep_pad_to_core_distance]
[-ignore_fixed]
objects
```

Data Types

<i>bounding_box</i>	rectangle
<i>offset</i>	rectangle
<i>scale_factor</i>	point
<i>object_width</i>	real
<i>object_height</i>	real
<i>util_factor</i>	real
<i>aspect</i>	real
<i>area_name</i>	real
<i>objects</i>	collection

ARGUMENTS

-bbox *bounding_box*

Specifies the new bounding box of the object. The *bounding_box* argument can be in either of the following formats: {x1 y1 x2 y2} or {x1 y1} {x2 y2}. The **-bbox** option cannot be used with any of the following options: **-delta**, **-scale**, **-width**, **-height**, **-utilization**, and **-aspect**.

-delta *offset*

Specifies the offset of the current bounding box of the object. The *offset* argument can be in either of the following formats: {x1 y1 x2 y2} or {x1 y1} {x2 y2}. The **-delta** option cannot be used with any of the following options: **-bbox**, **-scale**, **-width**, **-height**, **-utilization**, and **-aspect**.

-scale *scale_factor*

Specifies an x-axis and y-axis scale factor. All objects will be resized by this factor. The **-scale** option cannot be used with any of the following options: **-bbox**, **-delta**, **-width**, **-height**, **-utilization**, and **-aspect**. The scale factor must be positive and non-zero.

-width *object_width*
Specifies the width for a given object (or collection of objects). All objects are resized so that their bounding box has this width; however, the origin will not change. The **-width** option cannot be used with any of the following options: **-bbox**, **-delta**, **-scale**, **-utilization**, and **-aspect**. The **-width** and **-height** options can be used together.

-height *object_height*
Specifies the height for the given object (or collection of objects). All objects are resized so that their bounding box has this height; however, the origin will not change. The **-height** option cannot be used with any of the following options: **-bbox**, **-delta**, **-scale**, **-utilization**, and **-aspect**. The **-width** and **-height** options can be used together.

-utilization *util_factor*
Specifies the required utilization for the object. The object changes size based on *util_factor* value, but keeps the lower-left corner fixed and retains the original aspect ratio. The **-utilization** option cannot be used with any of the following options: **-bbox**, **-delta**, **-width**, **-height**, and **-aspect**. The utilization factor must be positive and non-zero.
Note: this option is usable only for soft macros and movebounds.

-aspect *aspect*
Specifies the required aspect for the object. The object changes size based on the *aspect* value, but keeps the lower-left corner fixed and retains the original area. The **-aspect** option cannot be used with any of the following options: **-bbox**, **-delta**, **-width**, **-height**, and **-utilization**.

-area *area_name*
Specifies a new area.

-keep_placement
Keeps existing placement if possible. This option is effective only when applied to the core or the die; it is ignored if applied on any other object. Cells in the core and I/O pad cells are re-placed if necessary. The relative positions of the cells are not guaranteed to be preserved, although an attempt is made to do that when possible. The output of the re-placement is not legalized. You must explicitly legalize the placement by using the **legalize_placement** command. The default is **false**.

-keep_pad_to_core_distance
Maintains the distance between the core and the pad cells; and, by implication, maintains the distance between the core and the die, thus forcing changes to the core and the die to be made together. If pad cells are absent then the core-to-die distance is still maintained. This option is effective only when applied to the core or the die; it is ignored if applied on any other object. The default is **false**.

-ignore_fixed
Resizes fixed objects. By default, fixed objects are not resized.

objects
Specifies a list of objects to be resized.

DESCRIPTION

This command resizes a list of objects to either an explicit bounding box, a delta from the current bounding box, an x and y scale, an explicit width and height, a size that gives a required utilization given a constant aspect ratio, or a size that gives a specified aspect ratio given a constant area. Only resizable objects can be used with this command. See the **get_edit_property** man page for a list of resizable objects.

Notes

Fixed objects are not moved unless you use the **-ignore_fixed** option.

Snapping is done automatically using global snap settings.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example resizes all selected objects so that they have an aspect ratio of 2.5.

```
prompt> resize_objects [get_selection]\n-aspect 2.5
```

The following example resizes all specified objects so that their lower-left corner is at the point {0 0} and they are 100 units wide and 100 units high.

```
prompt> resize_objects [get_selection]\n-bbox {0 0 100 100}
```

SEE ALSO

```
align_objects(2)\ndistribute_objects(2)\nexpand_objects(2)\nflip_objects(2)\nget_object_snap_type(2)\nmoving_objects(2)\nremove_objects(2)\nrotate_objects(2)\nset_object_snap_type(2)
```

resize_polygon

Returns a list of polygons whose edges have been pushed outwards or inwards (away from the area covered by the target polygon) by a specified distance.

SYNTAX

```
list resize_polygon
polygon
-size size
```

Data Types

<i>polygon</i>	list
<i>size</i>	double

ARGUMENTS

polygon

One polygon which is represented as a list of points. The format for a polygon is: $\{\{x_1\ y_1\}\ \{x_2\ y_2\}\ \dots\ \{x_N\ y_N\}\ \{x_1\ y_1\}\}$. Besides, a list of one polygon is also supported as input for this option, with the format: $\{\{\{x_1\ y_1\}\ \{x_2\ y_2\}\ \dots\ \{x_N\ y_N\}\ \{x_1\ y_1\}\}\}$. Pay attention that the valid polygon is rectilinear, so the adjacent points have one same coordinate. The coordinate unit is specified in technology file (usually it is micron).

-size size

Specified double value used to adjust the edges of the polygon

DESCRIPTION

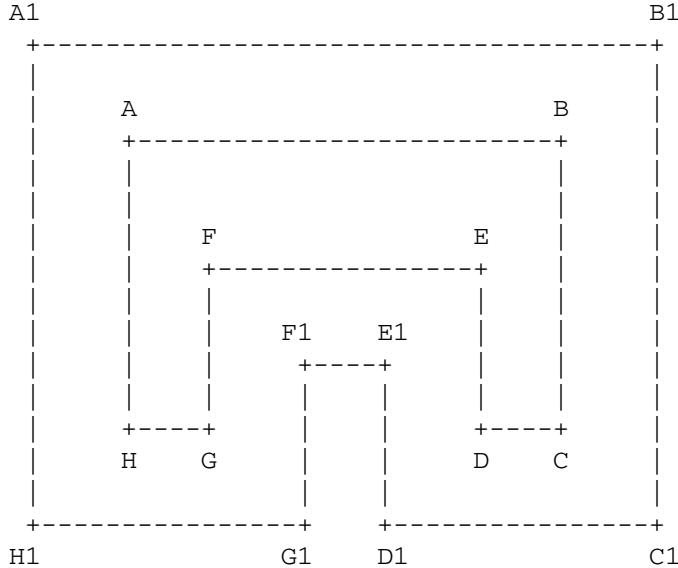

This command returns a list of polygons whose edges have been pushed outwards or inwards (away from the area covered by the target polygon) by a specified size. If the size is *positive*, the polygon will be oversized in which case the edges are pushed outwards and any gaps less than $2 * \text{size}$ units will be filled; otherwise the polygon will be undersized in which case the edges are pushed inwards. Each returned polygon will be represented as points list.

It is important to note that this command may return a list of more than one polygon which represents a disjoined rectilinear region if the size value is *negative*. So do not directly pass the result of this command as a parameter to another polygon command when negative size is specified. Tcl list command like **foreach**, **lindex** can be used to extract each polygon from the returned list, and then pass each polygon to other polygon command. But if the size value is positive, this command will return only one polygon, and then the result can be passed directly to other polygon commands, including **convert_from_polygons**, and **get_polygon_area**, **resize_polygon** and **compute_polygons**.

Before this command is used, the library should be opened.

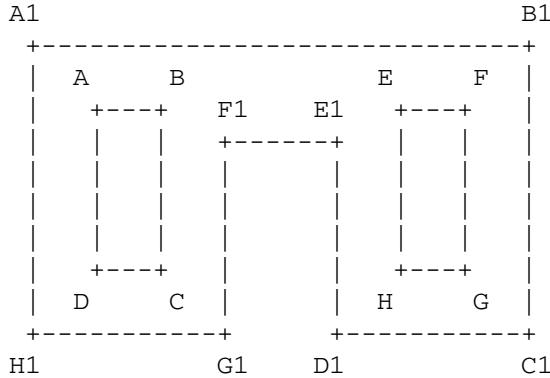

EXAMPLES

The following example returns the polygon A1-B1-C1-D1-E1-F1-G1-H1-A1 which is oversized from polygon A-B-C-D-E-F-G-H-A by size 10.

```
prompt> resize_polygon {{10 40} {60 40} {60 10} {50 10} {50 30} \
{20 30} {20 10} {10 10} {10 40}} -size 10
{{70 50} {70 0} {40} {40 20} {30 20} {30 0} {0 0} {0 50} {70 50}}
```

The following example returns two result polygons A-B-C-D-A and E-F-G-H-E after the polygon A1-B1-C1-D1-E1-F1-G1-H1-A1 is undersized by negative size 10.

```
prompt> resize_polygon {{0 45} {80 45} {80 0} {50 0} {50 30} {30 30} \
{30 0} {0 0} {0 45}} -size -10
{{10 35} {20 35} {20 10} {10 10} {10 35} } {{60 35} {70 35} {70 10} \
{60 10} {60 35}}
```

The following example passed the result of `resize_polygon` as a parameter to `resize_polygon` again.

```
prompt> resize_polygon -size -10 [resize_polygon {{10 40} {50 40} {50 10} \
{40 10} {40 30} {20 30} {20 10} {10 10} {10 40}} -size 10]
{10 40} {50 40} {50 10} {10 10} {10 40}
```

SEE ALSO

`convert_to_polygon(2)`
`convert_from_polygon(2)`
`compute_polygons(2)`

rotate_objects

Rotates one or more objects either geometrically or by setting the current orientation.

SYNTAX

```
new_objects rotate_objects
{-to orient
 | -by rotate
 | -mirror mirror}
[{-pivot point | -anchor anchor_point}]
[-ignore_fixed]
objects
```

Data Types

<i>orient</i>	string
<i>rotate</i>	string
<i>mirror</i>	string
<i>anchor_point</i>	string
<i>objects</i>	collection

ARGUMENTS

-to orient

Specifies the orientation of the object using either Design Exchange Format (DEF) or Synopsys notation.

The valid values are as follows:

**N, W, S, E, FN, FS, FE, FW
NW, NE, EN, ES, SE, SW, WN, WS**

The following groups of values are synonymous:

**N , NE
W , WN
S , SW
E , ES
FN, NW
FS, SE
FE, EN
FW, WS**

The **-to** option, **-by** and **-mirror** options are mutually exclusive. You must include one of these options.

The default is **N**.

-by rotate

Specifies the change in orientation of the object.

The valid values are as follows:

**90, 180, 270
CW90, CW180, CW270
CCW90, CCW180, CCW270**

The following values are synonymous:

**90 , CW270, CCW90
180, CW180, CCW180**

270, CW90 , CCW270

The -to option, -by and -mirror options are mutually exclusive. You must include one of these options.

-mirror *mirror}*

Specifies which direction to mirror the object:

X - Mirror X

Y - Mirror Y

The -to option, -by and -mirror options are mutually exclusive. You must include one of these options.

-pivot *point*

Specifies the point for pivoting.

The -pivot option and -anchor option are mutually exclusive. You can specify only one of them. If both are omitted, the default uses the center of the bounding box of the object or collection of objects.

This option only affects the -by option.

-anchor *anchor_point}*

Specifies the position of the pivot point in relation to the objects being rotated. One of:

ll - Lower Left

ur - Upper Right

center - Center

The -pivot option and -anchor option are mutually exclusive. You can specify only one of them. If both are omitted, the default uses the center of the bounding box of the object or collection of objects.

This option only affects the -by option.

The default is **center**.

-ignore_fixed

Specifies that fixed edit objects are rotated as well as the usual non-fixed edit ones.

objects

Specifies the list of objects to be rotated.

RETURNS

new_objects

Contains the list of rotated objects.

Note: In most cases this list is the same as the input list of objects but in some cases, e.g. when a vertical wire is rotated to become a new horizontal wire, the list may be different.

DESCRIPTION

This command rotates the specified objects around a pivot point by the specified absolute (-to option) or delta (-by option) orientation.

Transformable objects have their current orientation updated. Other resizable objects have their boundary rotated and reset.

See man page for get_edit_property command for a list of which objects can be transformed and which can have their boundary set.

Note: Snapping is done automatically using global snap settings.

DESCRIPTION

This command rotates and orients a list of objects rigidly about a given pivot point or computed point.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example rotates cell nand23 by 90 degrees clockwise:

```
prompt> rotate_objects -by CW90 [get_cells nand23]
```

SEE ALSO

```

get_object_snap_type(2)
set_object_fixed_edit(2)
get_object_fixed_edit(2)
```

route_area

Performs detail routing in specified area of the design.

SYNTAX

```
status route_area
-within {{llx1 lly1} {urx1 ury1} ....}
[-mode (initial_route | search_and_repair | optimize)]
[-loop num]
[-run_time_limit time]
```

Data Types

llx1	integer
lly1	integer
urx1	integer
ury1	integer
num	integer
time	integer

ARGUMENTS

```
-within {{llx1 lly1} {urx1 ury1} ....}
        Specifies either an area or areas to perform detail route.

-mode (initial_route | search_and_repair | optimize)
        Runs initial detail route or search & repair or optimization. Default is
        initial_route.

-loop num
        Specifies the number of search & repair loops. Default value is 20. Range is
        0 to 200. This option works with -mode values search_and_repair and optimize.

-run_time_limit time
        Specifies the runtime limit for detail route in minutes. The default value
        is -1 (it means no limit). Range of time is -1 to 500.
```

DESCRIPTION

This command is used to perform detail routing in a specified area or areas in the design. The option **-within** is mandatory.

Prerequisites

Global route the design using **route_global** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command performs area routing using the **-within**, **-mode**, **-loop**, and **-run_time_limit** options.

```
prompt> route_area -within {{100 100} {200 200}}\  
-mode search_and_repair -loop 5 -run_time_limit 50
```

SEE ALSO

`route_auto(2)`
`set_route_options(2)`

route_auto

Performs global routing, track assignment, detail routing, and search and repair in one step.

SYNTAX

```
status route_auto
[-no_global]
[-no_track]
[-no_detail]
[-search_repair_loop num]
[-effort (minimum | low | medium | high)]
[-save_after_global_route]
[-save_after_track]
[-save_after_detail_route]
[-num_cpus num]
```

Data Types

num integer

ARGUMENTS

```
-no_global
    Skips the global routing step.

-no_track
    Skips the track assignment step.

-no_detail
    Skips the detail routing step.

-search_repair_loop num
    Specifies the number of search and repair loops. The default is 0. The range
    is 0 to 500.

-effort (minimum | low | medium | high)
    Specifies the global route effort. The default is medium.

-save_after_global_route
    Saves the design after global route.

-save_after_track
    Saves the design after track assignment.

-save_after_detail_route
    Saves the design after detail route.

-num_cpus num
    Specifies the number of CPUs for distributed routing. The default is 0. The
    range is 0 to 500.
```

DESCRIPTION

This command is used to run global route, track assignment, detail route and search & repair in one step.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command runs auto route using the **-search_repair_loop**, **-effort**, **-save_after_global_route**, **-save_after_track**, **-save_after_detail_route**, and **-num_cpus** options.

```
prompt> route_auto -search_repair_loop 5\  
-effort high -save_after_global_route\  
-save_after_track -save_after_detail_route\  
-num_cpus 1
```

SEE ALSO

```
route_detail(2)  
route_global(2)  
route_search_repair(2)  
route_track(2)  
set_route_options(2)
```

route_detail

Performs detail routing on the design.

SYNTAX

```
status route_detail
[-track_assign (auto | skip)]
[-search_repair_loop num]
[-run_time_limit num]
[-num_cpus num]
```

Data Types

num integer

ARGUMENTS

```
-track_assign (auto | skip)
    Specifies if track assignment should be run. The default value is auto i.e.,
    the tool decides if track assignment should be run.

-search_repair_loop num
    Specifies the number of search and repair loops to be run. The default value
    is zero. Range is 0 to 500.

-run_time_limit num
    Specifies the cpu runtime limit in minutes. The default is no limit. Range
    is -1 to 500.

-num_cpus num
    Specifies the number of CPUs for distributed routing. Number must be >= 1.
```

DESCRIPTION

This command uses the general pathways suggested by the global routing and track assignment processes to route the nets (paths and contacts).

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example performs detail routing using the **-track_assign**, **-search_repair_loop**, **-run_time_limit**, and **-num_cpus** options.

```
prompt> route_detail -track_assign skip\
-search_repair_loop 5 -run_time_limit 50\
```

-num_cpus 2

SEE ALSO

`route_auto(2)`
`set_route_options(2)`

route_differential

Routes the nets in the specified differential groups.

SYNTAX

```
status route_differential
-groups group_names
[-ignore_global]
[-ignore_track_assign]
[-ignore_detail]
[-search_repair_loop int]
```

Data Types

<i>group_names</i>	list
<i>int</i>	integer

ARGUMENTS

```
-groups group_names
    Specified the name(s) of groups to route.

-ignore_global
    Do not run the global route on the specified group(s). Route the differential
    group(s) on default.

-ignore_track_assign
    Do not run the track assignment on the specified group(s). Route the
    differential group(s) on default.

-ignore_detail
    Do not run the detail route on the specified group(s). Route the differential
    group(s) on default.

-search_repair_loop int
    Enter in the number of Search and Repair loops that you want to control.
    Default is 5.
```

DESCRIPTION

Prerequisites : You need to define the differential group(s) with the `create_differential_group` command before using this command.

Route the nets in the given differential groups. This command uses the normal global route/track-assignment/detail route flow to route.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example is to route specified group, DGroup1, on all three routing phases (global route, track assignment, and detail route), and only try to search&repair once.

```
prompt> route_differential -groups DGroup1 -search_repair_loop 1
```

SEE ALSO

[create_differential_group\(2\)](#)

route_eco

Performs ECO routing on the design.

SYNTAX

```
status route_eco
[-no_global]
[-no_track]
[-no_detail]
[-auto]
[-region_based file]
[-distributed]
[-num_cpus num]
[-search_repair_loop num]
[-utilize_dangling_wires]
[-scope (global | local)]
[-reroute (modified_nets_only | modified_nets_first_then_others | any_nets)]
[-freeze_routing_on_layer name]
[-freeze_vias_on_frozen_metal]
```

Data Types

<i>file</i>	string
<i>num</i>	integer
<i>name</i>	string

ARGUMENTS

```
-no_global
    Skips global routing.

-no_track
    Skips track assignment.

-no_detail
    Skips detail routing.

-auto
    Decides which stages to run.

-region_based file
    Performs region based ECO routing on nets specified in file. Requires -auto.

-distributed
    Performs distributed region based ECO routing. Requires -auto and -region_based.

-num_cpus num
    Specifies number of cpus for distributed routing. Number must be >= 1.

-search_repair_loop num
    Specifies the number of search and repair loops. Default is 20. Range is 0
```

to 500.

-utilize_dangling_wires
Utilizes dangling wires. Default option is to discard.

-scope (global | local)
The default value is **global**. Use **global** when the design has DRC violations. The router not only connects the ECO nets but also fixes the DRC violations in the design. Use **local** option when the design is almost DRC clean and only the ECO nets need to be reconnected.

-reroute (modified_nets_only | modified_nets_first_then_others | any_nets)
The default value is **any_nets**. For the option **modified_nets_only**, the router freezes all the fully connected nets and tries to finish the routing by modifying only the nets with open ECO changes. This might cause the router to fail when fixing some violations. It is only suitable for very minor ECO changes.
For the option **modified_nets_first_then_others**, the router first freezes all the fully connected nets and tries to finish the routing by only modifying the nets with open ECO changes. When there are violations remaining, the router tries to reroute those fully connected nets to resolve the violations. This reduces the layout changes for minor ECO operations but is not suitable for major ECO changes.
For the option **any_nets**, The router reroutes any nets freely to fix all the DRC violations.

-freeze_routing_on_layer name
Freezes routing on the layers whose names are specified, ex m1. Default is none.

-freeze_vias_on_frozen_metal
Freezes vias on frozen metal layers. Works with **-freeze_routing_on_layer** option.

DESCRIPTION

This command performs routing for the broken nets. It runs global route, track assignment and detail route.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example performs ECO routing using the **-auto**, **-search_repair_loop**, **-utilize_dangling_wires**, **-scope**, and **-reroute** options.

```
prompt> route_eco -auto -search_repair_loop 5\
-utilize_dangling_wires -scope local\
-reroute modified_nets_first_then_others
```

SEE ALSO

`set_distributed_route(2)`
`set_route_options(2)`

route_flip_chip

Routes flip-chip nets on a single metal layer.

SYNTAX

```
status route_flip_chip
[-nets | -nets_in_file nets_file]
[-route_by_input_net_order ]
[-45_degree ]
-routing_layer layer
```

Data Types

<i>collection_of_nets</i>	collection
<i>nets_file</i>	string
<i>layer</i>	string

DATA TYPES

<i>nets_file</i>	string
<i>collection_of_nets</i>	collection
<i>layer</i>	string

ARGUMENTS

-nets {collection_of_nets}

Specifies the flip-chip nets to route.

-nets_in_file *nets_file*

Specifies the name of the file that contains the list of flip-chip nets to route.

This option and **-nets** are mutually exclusive; you can specify only one. If you do not specify either option, all flip-chip nets are routed.

-route_by_input_net_order

Routes the nets in the order in which they are specified in the **-nets** or **-net_in_file** option. By default, the tool sorts the nets based on their location.

-45_degree

The flip-chip router will route nets with 45 degree paths.

-routing_layer [layer]

Specifies the target layer for flip-chip routing. The range is m1 to m15. This option is necessary to be set.

DESCRIPTION

This command routes flip-chip nets by flip-chip router. In addition, it can rip up and reroute Manhattan wires.

Flip Chip Routing is a special application that shape based router routes nets on a single layer. It meets the following several requirements:

1. Providing routing tool to route, rip-up & reroute automatically
2. Providing user manual tool to handle open nets
3. Optimizing routing patterns to eliminate jogs and shorten wire length
4. Checking DRCs and opens for routed wires
5. Routing flip-chip nets on single layer.

The suggested flow for flip-chip routing is as follows:

1. Generate a file listing the flip-chip nets in the design by running the **write_flip_chip_nets** command.
2. Set the flip-chip routing options by running the **set_route_flip_chip_options** command.
3. Create stacked vias on the driver cells by running the **create_stack_via_on_pad_pin** command.
4. Verify that the stacked vias do not violate routing DRCS by running the **verify_route** command if you are using the classic router or **verify_zrt_route** if you are using Zroute.
5. Perform flip-chip routing by running the **route_flip_chip** command two or three times.
6. Display the remaining open nets by running the **display_flip_chip_route_flylines** command.
7. Manually route the open nets, if there are any, by using the **remove_flip_chip_route**, **push_flip_chip_route** and **route_flip_chip** commands.
8. After all flip-chip nets are routed, beautify the routed wires by running the **optimize_flip_chip_route** command.
9. Verify that the flip-chip nets do not violate routing DRCS by running the **verify_route** command if you are using the classic router or **verify_zrt_route** if you are using Zroute.

EXAMPLES

The following example routes the flip-chip nets specified in the RDLNetFile:

1. Route flip-chip nets recorded in a net file:
prompt> route_flip_chip -nets_in_file RDLNetFile -routing_layer m9
2. Route all flip-chip nets:
prompt> route_flip_chip

route_fp_proto

Performs quick global routing on the design.

SYNTAX

```
status route_fp_proto
[-effort (low | medium)]
[-congestion_map_only]
[-track_assignment]
```

ARGUMENTS

```
-effort (low | medium)
    Performs global routing. The default value of effort is low.

-congestion_map_only
    Creates only the congestion map without creating glinks.

-track_assignment
    Performs track assignment.
```

DESCRIPTION

This command maps general pathways through the design for each unrouted net (signal nets and clock nets). The global router uses a three-dimensional array of global routing cells to model the demand and capacity of global routing. The average height of the standard cells is used to create the height and width of each global routing cell.

During global routing, the tool assigns nets to the global routing cells through which they will pass. For each global routing cell, routing capacity is calculated according to the blockages, pins, and routing tracks inside the cell.

Although global routing does not assign the nets to the actual wire tracks, it notes the number of nets assigned to each global routing cell. The tool calculates the demand for wire tracks in each global routing cell and reports the overflows, which are the number of wire tracks still needed after the tool assigns nets to the available wire tracks in a global routing cell.

The tool might reduce overflows by detouring nets around congested areas and increasing the wire length. When a wire is prerouted, the tool checks to see whether it is completely connected. If the net is completely connected, the tool treats the net as a blockage; if the net is partially connected, the tool connects all parts of the net.

- * The tool treats power and ground nets as blockages.
- * The tool treats prerouted meshes and trunks as a single connection.

Make sure you examine the routing to see whether it is connected properly.

The **route_fp_proto** command uses the same algorithm as the **route_global** command but

internally sets some parameters to achieve a faster result, at some expense in quality. It is intended to give a quicker estimate of routability and congestion.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example performs proto routing using the **-effort** option.

```
prompt> route_fp_proto -effort medium
```

SEE ALSO

route_global(2)

route_global

Performs global routing on the design.

SYNTAX

```
status route_global  
[-effort (minimum | low | medium | high)]  
[-congestion_map_only]
```

ARGUMENTS

```
-effort (minimum | low | medium | high)  
        Performs global routing. The default value of effort is medium.  
  
-congestion_map_only  
        Create only the congestion map without creating glinks.
```

DESCRIPTION

This command maps general pathways through the design for each unrouted net (signal nets and clock nets). The global router uses a three-dimensional array of global routing cells to model the demand and capacity of global routing. The average height of the standard cells is used to create the height and width of each global routing cell.

During global routing, the tool assigns nets to the global routing cells through which they will pass. For each global routing cell, routing capacity is calculated according to the blockages, pins, and routing tracks inside the cell. Although global routing does not assign the nets to the actual wire tracks, it notes the number of nets assigned to each global routing cell.

The tool calculates the demand for wire tracks in each global routing cell and reports the overflows, which are the number of wire tracks still needed after the tool assigns nets to the available wire tracks in a global routing cell. The tool might reduce overflows by detouring nets around congested areas and increasing the wire length. When a wire is prerouted, the tool checks to see whether it is completely connected. If the net is completely connected, the tool treats the net as a blockage; if the net is partially connected, the tool connects all parts of the net.

- * The tool treats power and ground nets as blockages.
- * The tool treats prerouted meshes and trunks as a single connection.

Make sure you examine the routing to see whether it is connected properly.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command performs global routing using the **-effort** option.

```
prompt> route_global -effort high
```

SEE ALSO

`route_auto(2)`
`set_route_options(2)`

route_group

Performs routing on a group of nets in the design.

SYNTAX

```
status route_group
[-nets nets | -all_clock_nets]
[-no_global]
[-no_track]
[-no_detail]
[-search_repair_loop num]
[-utilize_dangling_wires]
[-trim_antenna_of_user_wires]
[-dont_optimize_route_pattern]
[-num_cpus num]
```

Data Types

<i>nets</i>	collection
<i>num</i>	integer

ARGUMENTS

```
-nets nets
      Specifies the collection of nets to be routed. This option and the -all_clock_nets option are mutually exclusive; you can specify only one.

-all_clock_nets
      Routes all clock nets. This option and the -nets option are mutually
      exclusive; you can specify only one.

-no_global
      Skips global routing.

-no_track
      Skips track assignment.

-no_detail
      Skips detail routing.

-search_repair_loop num
      Specifies the number of search and repair loops. The default is 5. The range
      is 0 to 500.

-utilize_dangling_wires
      Utilizes dangling wires. If you do not specify this option, dangling wires
      are discarded.

-trim_antenna_of_user_wires
      Trims wire segments of preroutes.
```

```
-dont_optimize_route_pattern
    Skips optimizing the route pattern.

-num_cpus num
    Specifies the number of CPUs for distributed routing. The default value is
    0. The range is 0 to 63.
```

DESCRIPTION

This command is used to route a specified group of nets. It is useful for discovering timing problems. For example, you can route clock and bus pins to prerouted clock and bus wires, then perform timing analysis on these nets. If the timing results are satisfactory, you can route the remaining nets by using the global routing, track assignment, and detail routing commands. You should route critical clocks nets before routing other signal nets so that the clock nets have the most direct routing.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example performs routing for a group of nets using the following options: **-all_clock_nets**, **-search_repair_loop**, **-utilize_dangling_wires**, **-trim_antenna_of_user_wires**, **-dont_optimize_route_pattern**, and **-num_cpus**.

```
prompt> route_group -all_clock_nets \
    -search_repair_loop 6 -utilize_dangling_wires \
    -trim_antenna_of_user_wires \
    -dont_optimize_route_pattern -num_cpus 1
```

SEE ALSO

```
route_detail(2)
route_global(2)
route_track(2)
route_search_repair(2)
set_route_options(2)
```

route_htree

Creates routes of H, I, or T (rotated H, rotated I, or rotated T) shape on the specified nets.

SYNTAX

```
status route_htreefp
-nets list_of_nets
-layers {horizontal_layer vertical_layer}
[-orientation list_of_three_orientation_values]
[-allow_off_grid]
[-allowViolation]
[-root root_buffer_of_the_H/I_tree]
[-mesh_net mesh_net]
```

Data Types

<i>list_of_nets</i>	collection
<i>horizontal_layer</i>	string
<i>vertical_layer</i>	string
<i>list_of_three_orientation_values</i>	collection

ARGUMENTS

```
-nets list_of_nets
    Indicates the list of nets to create routes. This is a required option.

-layers {horizontal_layer vertical_layer}
    Indicates the numbers or names of horizontal and vertical layers to be used
    for the routing. This is a required option.

-orientation list_of_three_orientation_values
    Specifies the preferred orientation to create the routes. You can provide up
    to three orientation values: H route, T route, and I route.

-allow_off_grid
    Enables the allowance for tracks that might not align to the routing grids.

-allowViolation
    Enables the allowance of DRC violations during routing.
```

DESCRIPTION

The route_htree command creates routes of the following shapes: H , H_90(rotated-H), I, I_90(rotated-I),T, T_90(rotated-T) routes, for example, T_90/T_180/T_270. The T shape is considered counter clockwise. For 5-pin nets (4 loads and 1 driver), the command creates routes of H or H_90 shape; for 3-pin nets, routes of I or I_90 shape; for 4-pin nets, routes of T, T_90, T_180, or T_270 shape. The 90 indication represents 90 degree counter clockwise rotation.

The /fBorientation/fP option specifies the default routing orientation for H, I, and

T routes. However, if the default does not produce good route, the command will try other possible orientations. If this option is not specified, the command determines a default orientation for the nets.

By default, the command selects tracks aligned to the routing grids during routing. If the command cannot find suitable on-grid tracks, it fails to Route. However, you can use the /fBallow_off_grid/fP option to select off-grid tracks in the proximity for routing.

The command does not create any routes when no DRC violation is found in creating the H, T, and I shaped routes. However, you can set the /fB-allowViolation/fP option for the command to create routes even with no DRC violation.

After creating route topology such as H/T/I/H_90/T_270, the comb router will connect pins to the nets using all available layers.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following shows an example of how to use **route_htree**:

```
prompt>route_htree -nets [get_nets {Htree_ck_gclkn_driver_x_L2* \
Htree_ck_gclkn_driver_x_L3*}] -layers {M6 M7}\
-orientation {H T_180 I_90}
```

For the nets specified in the above example, the **route_htree** will create H, inverted T, or rotated I shaped routes for 4-, 3- or 2-load-pin nets, respectively. The horizontal routes will be on M6 and vertical routes will be on M7. The routes will be aligned to tracks.

```
prompt>route_htree -nets [get_nets Htree_ck_gclkn_driver_x_L2*]\
-layers {M6 M7}\
-allow_off_grid
```

For the nets with the name prefix Htree_ck_gclkn_driver_x_L2 and Htree_ck_gclkn_driver_x_L3 in this example, appropriate routes such as H, T, or I shape will be created per the number of load pins. However, the default orientation is determined by the command. The routes might not be aligned with the tracks.

SEE ALSO

[add_clock_drivers\(2\)](#)

route_mesh_net

Routes the connections from the clock mesh wire grid to the associated drivers and loads.

SYNTAX

```
status route_mesh_net
-net
[-mode comb | fishbone]
[-max_backbone_fanout -max_backbone_fanout_value]
[-max_span max_span_value]
[-backbone_dir horizontal | vertical | both]
[-max_rc_delay float]
```

ARGUMENTS

```
-net net_name
    Specifies only one net to be routed.

-mode comb | fishbone
    Specifies the topology to be employed when you run the routing command. The comb mode has a thicker segment with many small segments coming off perpendicularly. The fishbone mode builds fishbone structures including the backbones grown from the mesh stripes and many fingers connecting the drivers and loads to the backbones. The default is comb mode.

-max_backbone_fanout -max_backbone_fanout_value
    The maximum number of fanouts on the backbone of one single fishbone structure. This option allows the user to control the number of loads on one single fishbone structure. This option only works with fishbone mode. By default, the max_backbone_fanout constraint is disabled.

-max_span max_span_value
    The maximum span of one fishbone structure. This options allows the user to control the size of fishbone structures. The span of a fishbone structure is defined as the width of the bounding box for the whole fishbone in the direction perpendicular to the backbone. This option only works with fishbone mode. By default, the max_span constraint is disabled.

-backbone_dir horizontal | vertical | both
    The direction of the backbones of fishbone structures. User can choose horizontal or vertical direction to route the backbone, or specify both to let the tool to decide the direction for each backbone. If both is specified, some backbones may be routed in horizontal direction and others may be routed in vertical direction. This option only works with fishbone mode. The default value of backbone_dir is both.
```

DESCRIPTION

To design a clock mesh, first you need to create a grid of relatively thick routing wires, which is called a mesh, and then allocate the buffers that drive the mesh.

Use the **route_mesh_net** command to attach the drivers and loads to the mesh.

FILES

No file is required or generated by this command.

LIMITATIONS

In general, the purpose of mesh nets is to reduce clock skew at the load points. The **route_mesh_net** command operates at a local level and does not attempt to reduce skew. That is, the connections to the routing mesh might vary in length and delay. For effective mesh results, create a mesh with enough horizontal and vertical wires so that no load is far apart from the mesh.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command is invoked after the wire mesh and all the drivers have been inserted.

```
prompt> route_mesh_net -net clk1 -mode balanced
```

SEE ALSO

```
create_clock_mesh(2)
add_clock_drivers(2)
compile_premesh_tree(2)
analyze_subcircuit(2)
compile_clock_tree(2)
```

route_opt

Performs simultaneous routing and post-route optimization on the design.

SYNTAX

```
status route_opt
[-effort low | medium | high]
[-xtalk_reduction]
[-only_xtalk_reduction]
[-skip_initial_route]
[-stage global | track | detail]
[-power]
[-incremental]
[-size_only]
[-optimize_wire_via]
[-area_recovery]
[-wire_size]
[-only_wire_size]
[-only_hold_time]
[-only_design_rule]
[-only_power_recovery]
[-only_area_recovery]
[-num_cpus number]
[-initial_route_only]
```

ARGUMENTS

-effort low | medium | high

Specifies the effort level for postroute optimizations in the route_opt flow. This option does not change the routing steps performed by route_opt. Valid values are **low**, **medium**, and **high**. In **high** effort, the tool is more aggressive during optimization and runs three optimization loops. The default effort level is **medium**.

-xtalk_reduction

Runs routing-based crosstalk reduction signal integrity (SI) optimization. By default, this option is off. This switch is applicable only if you enable signal integrity mode before running route_opt. You can enable signal integrity mode by setting either the **-delta_delay** or **-static_noise** option to true in **set_si_options**. By default, these options are set to false in **set_si_options**. If you specify the **-xtalk_reduction** option without enabling signal integrity mode, the tool issues an error message and stops.

-only_xtalk_reduction

Runs only routing-based crosstalk reduction. By default, this option is off. Similar to **-xtalk_reduction**, this switch is applicable only if you enable signal integrity mode running route_opt. If you specify this option without enabling signal integrity mode or if you specify any other options with the **-only_xtalk_reduction** option, the tool issues an error message and stops.

-skip_initial_route

Runs the topology-based optimization steps without initial routing. By

default, this option is off. Using this switch on a non-detail-routed design might generate erroneous results; therefore, you should verify that the design is fully routed before using this option. This option can not be used with the **-initial_route_only**, **-incremental**, or **-stage** options.

-stage global | track | detail

Specifies the stage to run routing and topology-based optimization. If you do not specify this option, the tool first runs global routing, track assignment, and detail routing. When you specify the stage "global", the tool runs only global routing along with optimization. When you specify the stage "track", the tool removes existing routing and re-runs global routing and track assignment along with optimization. When you specify the stage "detail", the tool runs detail routing along with optimization. By default, this option is off.

-power

Enables topology-based leakage power optimization as part of the optimization loop in the **route_opt** flow. By default, this option is off.

-incremental

Disables running of the initial routing steps. Runs only topology-based incremental optimization and ECO routing. By default, this option is off.

-size_only

Performs only sizing of cells in topology-based optimization. By default, this option is off. You can use this option for designs very sensitive to postroute optimization changes. You can control the sizing option by setting effort. Effort low will use **preserve_footprint** sizing. Effort medium will use **in_place** sizing. Effort high will use regular density based sizing. And the default effort is medium.

-optimize_wire_via

Runs an extra wire length and via count optimization. This option cannot be used with **route_opt** in Zroute mode. By default, this option is off.

-area_recovery

Enables area recovery for cells that are not on timing critical paths. By default, this option is off.

-wire_size

Enables the use of an additional technique of sizing the width of route segments to fix setup time violations during topology-based optimization. Needs existing NDR, and it can change netlist. Touched nets will have NDRs applied, and the applied NDRs will not be removed after wire sizing. By default, this option is off.

-only_wire_size

Performs only sizing of wires during topology-based optimization. Touched nets will have NDRs applied, and the applied NDRs will not be removed after wire sizing. This option can be used only with the **-incremental** option. By default, this option is off.

-only_hold_time

Specifies that only hold time violations are fixed. Applicable only if hold fixing is enabled using the **set_fix_hold** command before running **route_opt**.

This switch can be used only with the **-incremental** option. By default, this option is off.

-only_design_rule

If **-only_design_rule** is specified, the tool performs only design rule fixing, and timing optimizations are not performed. This option can be used only with the **-incremental** option. By default, this option is off.

-only_power_recovery

Specifies that only leakage power optimizations are performed. This option can be used only with the **-incremental** option. By default, this option is off.

-only_area_recovery

Specifies that only area optimizations are performed. This option can be used only with the **-incremental** option. By default, this option is off.

-num_cpus number

Specifies the number of CPUs for detail routing and search and repair routing. You can use up to 63 CPUs. By default, this option is off. This option is applicable only if you set up multiple CPU mode by using the **set_distributed_route** command prior to running. This option cannot be used with route_opt in Zroute mode. **route_opt**.

-initial_route_only

Runs only the initial routing stage (it runs global routing, track assignment, detail routing, and search and repair). By default, this option is off.

DESCRIPTION

This command performs simultaneous routing and postroute optimization on the current design. The output of this command is a postroute optimized design. The route_opt flow runs differently depending on whether signal integrity mode is enabled.

A default (medium effort) signal-integrity-enabled route_opt flow includes:

1. Initial routing: Global routing, track assignment, detail routing, and search and repair
2. Topology-based optimization (adaptive) without considering signal integrity
3. Topology-based signal integrity optimization

A default (medium effort) signal-integrity-disabled route_opt flow includes:

1. Initial routing: Global routing, track assignment, detail routing, and search and repair
2. Topology-based optimization without considering signal integrity

You can add routing-based crosstalk reduction and wire length and via count optimization to the default flow by using the **-xtalk_reduction** and **-optimize_wire_via** options. The signal-integrity-enabled route_opt flow is then changed to:

1. Initial routing: Global routing, track assignment, detail routing, and search and repair

2. Optimization of wire length and via count
3. Topology-based optimization (adaptive) without considering signal integrity
4. Routing-based crosstalk reduction
5. Topology-based signal integrity optimization

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following example runs initial routing and stops without running optimization:

```
prompt> route_opt -initial_route_only
```

The following example performs only global routing:

```
prompt> route_opt -initial_route_only -stage global
```

The following example performs only global routing and track assignment:

```
prompt> route_opt -initial_route_only -stage track
```

The following example runs only detail routing and search and repair:

```
prompt> route_opt -initial_route_only -stage detail
```

The following example runs only optimization and skips the initial routing steps:

```
prompt> route_opt -skip_initial_route
```

The following example runs only incremental optimization:

```
prompt> route_opt -incremental
```

The following example runs routing-based crosstalk reduction in addition to the default route_opt signal integrity flow:

```
prompt> route_opt -xtalk_reduction
```

`clock_opt(2)`
`extract_rc(2)`
`place_opt(2)`
`set_route_opt_strategy(2)`

route_rc_reduction

Optimizes the timing and crosstalk on a fully-routed design, based on the detail routing results. This command works only on completely detail-routed designs that include all the necessary timing information.

SYNTAX

```
status route_rc_reduction
[-slack_target slack_target_number]
[-setup_slack_effort optimize | preserve]
[-max_transition]
[-max_capacitance]
[-crosstalk_noise]
[-run_time_limit number]
[-opt_delay_loop number]
[-opt_delay_search_repair_loop number]
```

Data Types

<i>slack_target_number</i>	integer
<i>number</i>	integer

ARGUMENTS

```
-slack_target slack_target_number
    Specifies the slack target of delay opt (default is 0.1).

-setup_slack_effort optimize | preserve
    Specifies the effort level (default is optimize).

-max_transition
    Considers maximum transition constraints during optimization.

-max_capacitance
    Considers maximum capacitance constraints during optimization.

-crosstalk_noise
    Considers crosstalk noise constraints during optimization.

-run_time_limit number
    Specifies the run time limit in minutes (default is no limit).

-opt_delay_loop number
    Specifies the total number of optimization loops (default is 10).

-opt_delay_search_repair_loop number
    Specifies the number of search repair loops (default is 5).
```

DESCRIPTION

This command calls the timer to analyze the critical paths and then uses various

techniques to improve the design timing and minimize the crosstalk problems.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example optimizes the timing to 0.22 and only runs 3 opt loops.

```
prompt> route_rc_reduction\  
-slack_target 0.22 -opt_delay_loop 3
```

SEE ALSO

set_si_options (2)

route_search_repair

Performs a search and repair routing operation on the design.

SYNTAX

```
status route_search_repair
[-loop num]
[-run_time_limit num]
[-reset_width]
[-rerun_drc]
[-reset_min_max_layer]
[-trim_antenna_of_user_wires]
[-dont_connect_tie_off]
[-ignore_open_nets]
[-num_cpus num]
```

Data Types

num integer

ARGUMENTS

```
-loop num
      Specifies the number of search and repair loops. The default is 50. The range
      is 0 to 1000.

-run_time_limit num
      CPU runtime limit in minutes. The default is no limit. The range is -1 to 500.

-reset_width
      Resets the default width.

-rerun_drc
      Runs the design rule checker before starting search and repair.

-reset_min_max_layer
      Resets the min-max layer setting.

-trim_antenna_of_user_wires
      Trims wire segments of preroute wires.

-dont_connect_tie_off
      Specifies not to connect pg or clock.

-ignore_open_nets
      Specifies not to connect partially routed wire segments.

-num_cpus num
      Specifies the number of cpus for distributed routing. It must be >= 1. The
      range is 0 to 63.
```

DESCRIPTION

This command allows you to run incremental search and repair routing passes after detail routing. During these routing passes, the tool searches for design rule violations and reroutes wires in an effort to avoid violations.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example performs search and repair using the following options: **-loop**, **-run_time_limit**, **-reset_width**, **-rerun_drc**, **-reset_min_max_layer**, **-trim_antenna_of_user_wires**, **-dont_connect_tie_off**, **-ignore_open_nets**, and **-num_cpus**.

```
prompt> route_search_repair -loop 5\  
-run_time_limit 50 -reset_width\  
-rerun_drc -reset_min_max_layer  
-trim_antenna_of_user_wires\  
-dont_connect_tie_off\  
-ignore_open_nets -num_cpus 1
```

SEE ALSO

[route_auto\(2\)](#)
[route_detail\(2\)](#)
[set_route_options\(2\)](#)

route_spreadwires

Spreads wires in the opened cell for DFM.

SYNTAX

```
route_spreadwires
[-timing_driven]
[-search_repair_loop number_of_loops]
[-setup_slack_threshold setup_time]
[-min_jog_length min_ratio]
[-num_cpus number_of_cpus]
```

Data Types

<i>number_of_loops</i>	integer
<i>setup_time</i>	double
<i>min_ratio</i>	integer
<i>number_of_cpus</i>	integer

ARGUMENTS

-timing_driven
Calls the timing engine to get critical nets (setup slack lower than the threshold). Locks these critical nets from spreading.

-search_repair_loop *number_of_loops*
Sets the number of loops that search and repair runs. By default, the *number_of_loops* value is 10.

-setup_slack_threshold *setup_time*
Sets setup time threshold. By default, the value of *setup_time* is 0.0. The higher the threshold is, the more nets are set as critical.

-min_jog_length *min_ratio*
Sets the minimal value of the ratio of jog length to layer pitch. By default, the *min_ratio* value is 2.

-num_cpus *number_of_cpus*
Specifies the number of cpus for distributed routing. The *number_of_cpus* value must be greater than or equal to 1.

DESCRIPTION

This command spreads wires in the opened cell for DFM. When spreading, a piece of original wire is broken and pushed away and jog wires are created at both ends to maintain a connection.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example performs wire spreading using the **search_repair_loop**, **timing_driven**, **setup_slack_threshold**, and **widen_wires** options.

```
prompt> route_spreadwire -widen_wires\  
-search_repair_loop 6 -timing_driven\  
-setup_slack_threshold 0.15
```

SEE ALSO

`route_search_repair(2)`

route_track

Assigns wires to tracks in the design.

SYNTAX

```
status route_track
```

DESCRIPTION

Before running the detail router, run **route_track** to specify which tracks within each global routing cell are to be used for each net. Track assignment operates on the entire design at once; it can make long routes straight and reduce the number of vias, whereas the detail router routes a small area at a time. After track assignment finishes, all nets are routed. There are many violations, particularly where the routing connects to pins. The detail router cleans up the violations.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command performs track assignment:

```
prompt> route_track
```

SEE ALSO

```
set_route_options(2)  
route_auto(2)
```

route_widen_wire

Performs wire widening for wires of signal nets.

SYNTAX

```
status route_widen_wire
[-search_repair_loop number_of_loops]
[-nonuniform_widening]
[-timing_driven]
[-setup_slack_threshold value_of_setup_slack_threshold]
[-hold_slack_threshold value_of_hold_slack_threshold]
```

Data Types

<i>number_of_loops</i>	integer
<i>value_of_setup_slack_threshold</i>	float
<i>value_of_hold_slack_threshold</i>	float

ARGUMENTS

-search_repair_loop *number_of_loops*

Specifies the number of search and repair loops for design rule checking (DRC) fixes after wires are widened ($0 \leq \text{number_of_loops} \leq 100$). By default, the value of *number_of_loops* is **10**.

-nonuniform_widening

Attempts to break each wire according to its neighbor wire patterns, and then tries to widen it with a different width for each piece of wire.

-timing_driven

Prevents widening of the wires of timing-driven nets. Widened wires impact both the setup and hold time of a net. Timing-critical nets should not be widened.

-setup_slack_threshold *value_of_setup_slack_threshold*

Sets the setup time threshold. Default value is 0.0. The higher the threshold, the more nets will be set as critical.

-hold_slack_threshold *value_of_hold_slack_threshold*

Sets the hold time threshold. Default value is 0.0. The higher the threshold, the more nets will be set as critical.

DESCRIPTION

This command attempts to widen the wires of all signal nets. The width of a wire is limited during the widening operation so that the wire does not exceed 1.5 times the default wire width or become a fat wire. A fat wire is one whose width exceeds the threshold of fat degree defined in the technology file.

The **-timing_driven** option freezes the nets whose setup time slack or hold time slack values are lower than their respective threshold values. Wires of frozen nets are

not widened. This can preserve timing results of timing-critical nets.

The **-setup_slack_threshold** and **-hold_slack_threshold** options must be used together with the **-timing_driven** option. These options provide the interface to adjust the range of timing-critical nets, which will be frozen from being widened.

After wire widening is done, the internal search and repair engine is triggered to fix DRC violations introduced by **route_widen_wire**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example performs wire widening followed by 20 search and repair loops.

```
prompt> route_widen_wire -search_repair_loop 20
```

SEE ALSO

[route_spreadwires\(2\)](#)

route_widen_wire
2056

route_zrt_auto

Performs global routing, track assignment, and detail routing in one step.

SYNTAX

```
status route_zrt_auto
[-max_detail_route_iterations num]
[-reuse_existing_global_route true | false]
[-stop_after_track_assignment true | false]
[-save_after_global_route true | false]
[-save_after_track_assignment true | false]
[-save_after_detail_route true | false]
[-save_cell_prefix name]
```

Data Types

<i>num</i>	integer
<i>name</i>	string

ARGUMENTS

```
-max_detail_route_iterations num
    Specifies the maximum number of detail routing iterations. You can specify
    an integer between 1 and 1000.
    By default, the maximum number of iterations for the detail routing command
    (40) is used.

-reuse_existing_global_route true | false
    Enables or disables incremental global routing.
    By default (false), the global router deletes all existing global routes from
    the design before routing starts.
    If this option is set to true, the global router keeps and reuses existing
    global routes.

-stop_after_track_assignment true | false
    Controls whether the command runs detail routing.
    By default (false), the command runs global routing, track assignment, and
    detail routing.
    If this option is true, the command skips detail routing and runs only global
    routing and track assignment.

-save_after_global_route true | false
    Controls whether the design is saved after global routing.
    The default value is false.

-save_after_track_assignment true | false
    Controls whether the design is saved after track assignment.
    The default value is false.

-save_after_detail_route true | false
    Controls whether the design is saved after detail routing.
    The default value is false.
```

```
-save_cell_prefix name
    Specifies the prefix to use when saving the design. For example, if you
    specify "foo" as the prefix, the name of the design saved after global routing
    is foo_icGRT.
    The default prefix is auto.
```

DESCRIPTION

The **route_zrt_auto** command runs global routing, track assignment, and detail routing in one step. This command runs faster than using the basic commands because it does not access the disk between the different stages. The results are comparable to the basic flow (it might not be identical because the shapes could be ordered differently when the design is saved to disk).

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following command runs automatic routing using the **-save_after_global_route**, **-save_after_detail_route**, **-save_cell_prefix**, and **-max_detail_route_iterations** options:

```
prompt> route_zrt_auto \
    -save_after_global_route true \
    -save_after_detail_route true \
    -save_cell_prefix auto \
    -max_detail_route_iterations 15
```

SEE ALSO

```
route_zrt_global(2)
route_zrt_track(2)
route_zrt_detail(2)
set_route_zrt_common_options(2)
set_route_zrt_detail_options(2)
set_route_zrt_track_options(2)
```

route_zrt_clock_tree

Performs routing on the clock nets in the design using Zroute.

SYNTAX

```
status route_zrt_clock_tree
[-utilize_dangling_wires false|true]
[-reuse_existing_global_route false|true]
[-max_detail_route_iterations int]
```

ARGUMENTS

There are no arguments to this command.

DESCRIPTION

The **route_zrt_clock_tree** command route the clock nets in the current design using Zroute.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following example shows the default command output.

```
prompt> route_zrt_clock_tree
```

SEE ALSO

```
set_route_mode_options(2)
route_zrt_group(2)
```

route_zrt_detail

Performs detail routing on the design.

SYNTAX

```
status route_zrt_detail
[-max_number_iterations count]
[-coordinates {{llx1_lly1}_{urx1_ury1}...}]
[-incremental true | false]
[-initial_drc_from_input true | false]
[-start_iteration int]
```

Data Types

<i>count</i>	integer
<i>int</i>	integer

ARGUMENTS

-max_number_iterations *count*

Specifies the maximum number of routing iterations. The detail router terminates after the maximum number of iterations or when it detects a lack of progress, whichever occurs first.

Limiting the number of routing iterations can provide faster results; however, it might cause the detail router to terminate before the design rule constraint (DRC) violations are resolved.

The range is from 1 to 1000.

The default value is 40.

To disable automatic termination of detail routing (and force Zroute to complete the maximum number of iterations), use the

set_route_zrt_detail_options -force_max_number_iterations true command.

-coordinates {{*llx1_lly1*}_{*urx1_ury1*}...}

Specifies the routing area. It supports multiple rectangle routing areas. The coordinates set should be in user unit.

The -

coordinates option is not set by default, in which case the full chip will be routed.

-incremental true | false

If true (default is false), the router performs incremental mode routing. By default the router starts from the iteration number that detail routing ends

with last time the cell was routed. If -

start_iteration is set, the router will

start from the iteration number specified in this option. By default the router

will re-check DRC in the beginning. If -

initial_drc_from_input is set as true,

the router will skip the initial DRC checking and start with the DRC information

stored in the cell.

-initial_drc_from_input true | false

When true, the detail router uses the DRC information in the cell as the initial DRC information. Use this option very carefully; set it to true only if you are absolutely sure that the the DRCs in the cell are up-to-date.

The default is false.

-start_iteration int

Specifies the start iteration for detail route. Detail route iterations will run from **start_iteration** number up to the iteration number specified by **max_number_iterations**.

The range is from 0 to 1000.

The default is 0.

DESCRIPTION

This command performs detail routing on a design. You run this command after running the **route_zrt_track** command.

By default, **route_zrt_detail** analyzes the design rule constraint (DRC) violations in the entire design, and then resolves those violations. To skip the analysis and use the violations stored in the database as the starting point, set the option - **initial_drc_from_input** to **true**. The user should do this only if the violations stored in the database are current and correct.

The behavior of this command is influenced by the options set by the **set_route_zrt_detail_options** and **set_route_zrt_common_options** commands.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following command performs detail routing:

```
prompt> route_zrt_detail
```

The following command performs detail routing with a maximum of 3 iterations:

```
prompt> route_zrt_detail -max_number_iterations 3
```

The following command performs detail routing in the rectangle areas [0 0 50.0 60.2] and [100.0 100.0 120.2 110.2]:

```
prompt> route_zrt_detail -coordinates {{0 0} {50.0 60.2} {100.0 100.0} {120.2 110.2}}
```

The following command performs incremental detail routing:

```
prompt> route_zrt_detail -incremental true
```

The following command uses drc information in the cell and starts with iteration 1:

```
prompt> route_zrt_detail -initial_drc_from_input true  
-start_iteration 1
```

SEE ALSO

`set_route_zrt_detail_options(2)`
`set_route_zrt_common_options(2)`
`route_zrt_auto(2)`
`route_zrt_global(2)`
`route_zrt_track(2)`

route_zrt_eco

Performs ECO routing on the design.

SYNTAX

```
status route_zrt_eco
[-max_detail_route_iterations count]
[-nets list]
[-open_net_driven true | false]
[-reroute modified_nets_only | modified_nets_first_then_others | any_nets]
[-reuse_existing_global_route true | false]
[-utilize_dangling_wires true | false]
```

Data Types

count integer
list list

ARGUMENTS

-max_detail_route_iterations count

Specifies the maximum number of detail routing iterations. You can specify an integer between 1 and 1000.

By default, the maximum number of iterations for the detail routing command (40) is used.

-nets list

Specifies the nets on which to perform ECO routing. The command first connects the open nets in this list, and then fixes design rule violations in their neighborhood.

When you specify the **-nets** option, the command always treats the **-open_net_driven** option as false, regardless of its actual setting.

By default, this command works on all nets in the design.

-open_net_driven true | false

Controls whether ECO route fixes DRC violations for the whole design (default) or only in the neighborhood of the open nets.

By default (false), ECO route connects the open nets in the design and fixes design rule violations for the entire design.

When true, ECO route connect the open nets in the design and fixes DRC violations only in the neighborhood of the open nets.

-reroute modified_nets_only | modified_nets_first_then_others | any_nets

Controls which nets are rerouted.

The definition for each mode is

* **any_nets** (default)

The router reroutes any nets freely to fix all the DRC violations.

* **modified_nets_only**

The router freezes all the fully connected nets and tries to finish the routing by modifying only the nets with open ECO changes. This might cause the router to fail when fixing some violations. It is only suitable for very minor ECO changes.

- * **modified_nets_first_then_others**
The router first freezes all the fully connected nets and tries to finish the routing by modifying only the nets with open ECO changes. When there are violations remaining, the router tries to reroute those fully connected nets to resolve the violations. This reduces the layout changes for minor ECO operations but is not suitable for major ECO changes.

-reuse_existing_global_route true | false
Enables or disables incremental global routing.
By default (false), the global router deletes all existing global routes from the design before routing starts.
If this option is set to true, the global router keeps and reuses existing global routes.

-utilize_dangling_wires true | false
Controls whether the router tries to reuse the dangling routes as much as possible to fix the opens.
The default value is true.

DESCRIPTION

The **route_zrt_eco** command performs ECO routing. It first connects the open nets and then fixes the DRC violations. The options control which nets are connected and on which areas of the chip the DRCs are fixed.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following command performs ECO routing using the **-nets**, **-utilize_dangling_wires**, and **-reroute** options.

```
prompt> route_zrt_eco -nets {n1 n2 n3} -utilize_dangling_wires true \
-reroute modified_nets_first_then_others
```

SEE ALSO

set_route_zrt_detail_options(2)

route_zrt_global

Performs global routing on the design.

SYNTAX

```
status route_zrt_global
[-effort minimum | low | medium | high]
[-congestion_map_only true | false]
[-reuse_existing_global_route true | false]
```

ARGUMENTS

-effort minimum | low | medium | high
Specifies the effort used to perform global routing.
By default, the global router uses medium effort.

-congestion_map_only true | false
Creates the congestion map without creating glinks.
The default value is false.

-reuse_existing_global_route true | false
Enables or disables incremental global routing.
By default (false), the global router deletes all existing global routes from the design before routing starts.
If this option is set to true, the global router keeps and reuses existing global routes.

DESCRIPTION

The **route_zrt_global** command maps general pathways through the design for each unrouted net (signal nets and clock nets). The global router uses a three-dimensional array of global routing cells to model the demand and capacity of global routing. The average height of the standard cells is used to create the height and width of each global routing cell. During global routing, the tool assigns nets to the global routing cells through which they pass. For each global routing cell, routing capacity is calculated according to the blockages, pins, and routing tracks inside the cell. Although global routing does not assign the nets to the actual wire tracks, it notes the number of nets assigned to each global routing cell. The tool calculates the demand for wire tracks in each global routing cell and reports the overflows, which are the number of wire tracks still needed after the tool assigns nets to the available wire tracks in a global routing cell. The tool might reduce overflows by detouring nets around congested areas and increasing the wire length. When a wire is prerouted, the tool checks to see whether it is completely connected. If the net is completely connected, the tool treats the net as a blockage; if the net is partially connected, the tool connects all parts of the net.

- * The global router treats power and ground nets as blockages.
- * The global router treats prerouted meshes and trunks as a single connection. Make sure you examine the routing to see whether they are connected properly.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following command performs global routing using high effort:

```
prompt> route_zrt_global -effort high
```

SEE ALSO

`set_route_zrt_global_options(2)`
`route_zrt_auto(2)`

route_zrt_group

Performs routing on a group of nets in the design.

SYNTAX

```
status route_zrt_group
[-max_detail_route_iterations num]
[-nets nets | -all_clock_nets]
[-stop_after_global_route true | false]
[-reuse_existing_global_route true | false]
[-utilize_dangling_wires true | false]
-from_file file_name
```

Data Types

num	integer
nets	collection

ARGUMENTS

-max_detail_route_iterations num
Specifies the maximum number of detail routing iterations. You can specify an integer between 1 and 1000.
By default, the maximum number of iterations for the detail routing command (40) is used.

-nets nets
Specifies the nets to be routed.
You must specify the nets on which to run this command by specifying at least one of the following options: **-nets**, **-all_clock_nets**, and **-from_file**. The **-nets** and **-all_clock_nets** options are mutually exclusive; you can specify only one. You can specify the **-from_file** option in addition to the **-nets** option.

-all_clock_nets
Routes all clock nets.
You must specify the nets on which to run this command by specifying at least one of the following options: **-nets**, **-all_clock_nets**, and **-from_file**. If you specify the **-all_clock_nets** option, you cannot specify the **-nets** or **-from_file** option.

-stop_after_global_route true | false
Controls whether the router stops after global route or continues all the way to detail route.
The default value is false which means it will continue all the way to detail route.

-reuse_existing_global_route true | false
Enables or disables incremental global routing.
By default (false), the global router deletes all existing global routes from the design before routing starts.
If this option is set to true, the global router keeps and reuses existing global routes.

```
-utilize_dangling_wires true | false
    Controls whether the router tries to reuse the dangling routes as much as
    possible.
    The default value is true.

-from_file file_name
    Routes the nets specified by name in the file.
    If the specified file either does not exist or does not contain any valid
    nets, the tool generates an error and indicates the source of the problem.
    You must specify the nets on which to run this command by specifying at least
    one of the following options: -nets, -all_clock_nets, and -from_file. You can
    specify the -from_file option in addition to the -nets; however, the -
    from_file option cannot be used with the -all_clock_nets option.
```

DESCRIPTION

The **route_zrt_group** command is used to route a specified group of nets.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following command performs routing for all clock nets using the **-max_detail_route_iterations** and **-utilize_dangling_wires** options.

```
prompt> route_zrt_group -all_clock_nets \
    -max_detail_route_iterations 6 \
    -utilize_dangling_wires true
```

SEE ALSO

route_zrt_global(2)
route_zrt_track(2)
route_zrt_detail(2)

route_zrt_track

Performs track assignment on the design.

SYNTAX

```
status route_zrt_track
```

ARGUMENTS

This command has no arguments.

DESCRIPTION

This command performs track assignment on a global routed design. Run this command after running **route_zrt_global** and before running **route_zrt_detail** to assign wires to the routing tracks defined in the technology file. Track assignment operates on the entire design at once; whereas the detail router routes a small area at a time. Track assignment can make long routes straight and reduce the number of vias. After track assignment finishes, all nets are routed, but there are many violations, particularly where the routing connects to pins. The detail router fixes the violations.

The behavior of this command is influenced by options set by the **set_route_zrt_track_options** and **set_route_zrt_common_options** commands.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following command performs track assignment.

```
prompt> route_zrt_track
```

SEE ALSO

```
set_route_zrt_track_options(2)

route_zrt_detail(2)
```

rp_group_inclusions

Returns a collection of relative placement groups that are directly included in the specified relative placement groups.

SYNTAX

```
collection rp_group_inclusions
[rp_groups]
```

Data Types

rp_groups list or collection

ARGUMENTS

rp_groups
Specifies the relative placement groups in which to search for directly included relative placement groups.
If you do not specify this argument, the tool searches all relative placement groups for directly included relative placement groups.

DESCRIPTION

The **rp_group_inclusions** command returns a collection containing all relative placement groups that are directly included in the relative placement groups specified in *rp_groups*. If you do not specify *rp_groups*, the command returns a collection containing all included relative placement groups. This command is supported only for designs that do not contain multiply-instantiated designs.

A group directly includes another group if the group was added by using the **add_to_rp_group -hierarchy** command without also using the **-instance** option.

If no groups are found, an empty string is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **rp_group_inclusions** command:

```
prompt> get_rp_groups
{b::top a0::a0_group b::u_top/a1_group
 b::u_top/a1_group_include b::u_nxt/a1_group
 b::a1_group_include a1::a1_group}

prompt> rp_group_inclusions
```

```
{b::u_top/a1_group b::u_nxt/a1_group}

prompt> rp_group_inclusions a0::a0_group

prompt> rp_group_inclusions top
{b::u_top/a1_group b::u_nxt/a1_group}

prompt> remove_rp_groups -all -quiet
1

prompt> rp_group_inclusions
```

rp_group_instantiations

Returns a collection of relative placement groups that are instantiated in any of the specified relative placement groups.

SYNTAX

```
collection rp_group_instantiations
[rp_groups]
```

Data Types

rp_groups list or collection

ARGUMENTS

rp_groups
Specifies the relative placement groups in which to search for instantiated relative placement groups.
If you do not specify this argument, the tool searches all relative placement groups for instantiated relative placement groups.

DESCRIPTION

The **rp_group_instantiations** command returns a collection containing all relative placement groups that are instantiated in the relative placement groups specified in *rp_groups*. If you do not specify *rp_groups*, the command returns a collection containing all instantiated relative placement groups.

This command is supported only for designs that do not contain multiply-instantiated designs.

A group instantiates another group if the group was added by using the **add_to_rp_group -hierarchy -instance** command.

If no groups are found, an empty string is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **rp_group_instantiations** command:

```
prompt> get_rp_groups
{b::top a0::a0_group b::u_top/a1_group
 b::u_top/a1_group_include b::u_nxt/a1_group
 b::a1_group_include a1::a1_group}
```

```
prompt> rp_group_instantiations
{a0::a0_group}

prompt> rp_group_instantiations b::a1_group_include
{a1::a1_group}

prompt> remove_rp_groups -all -quiet
1

prompt> rp_group_instantiations
```

[rp_group_references\(2\)](#)

rp_group_references

Returns a collection of cells that are directly included by the specified relative placement groups.

SYNTAX

```
collection rp_group_references
[rp_groups]
[-leaf | -instance]
```

Data Types

rp_groups list or collection

ARGUMENTS

<i>rp_groups</i>	Specifies the relative placement groups in which to find directly included cells.
-leaf -instance	Specifies whether only leaf cells or only hierarchical cells are returned. By default, both leaf and hierarchical cells are returned.

DESCRIPTION

The **rp_group_references** command returns a collection containing all cells that are directly included in the relative placement groups specified in *rp_groups*. If you do not specify *rp_groups*, the command returns a collection containing all cells that are directly included in any relative placement group.

This command is supported only for designs that do not contain multiply-instantiated designs.

When you specify the **-leaf** option, only leaf cells are returned. When you specify the **-instance** option, only hierarchical cells are returned. An included relative placement group, unlike an instantiated relative placement group, does not have a hierarchical cell associated with it, so the **rp_group_references** command does not report included hierarchical relative placement groups.

A group directly includes a leaf cell if the cell was added to that group using the **add_to_rp_group -leaf** command.

A group directly includes a hierarchical cell if the cell was used to hierarchically instantiate another group using the **add_to_rp_group -instance** command.

If no cells are found, an empty string is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **rp_group_references** command:

```
prompt> get_rp_groups
{b::top a0::a0_group b::u_top/a1_group
 b::u_top/a1_group_include b::u_nxt/a1_group
 b::a1_group_include a1::a1_group}

prompt> rp_group_references
{u_mid u_bot}

prompt> all_rp_references u_0 -design a0
{a0::a0_group}

prompt> rp_group_references a0::a0_group
{u_bot/u_1 u_bot/u_0}

prompt> remove_rp_groups -all -quiet
1

prompt> rp_group_references
```

run_parallel_jobs

Runs parallel jobs controlled by the tool. It is typically used to invoke the tool on a group of subblocks in a hierarchical design.

SYNTAX for Submitting a Job

```
status run_parallel_jobs

[-serial
 | -parallel num_jobs] [-stage_names stage_name_list]
[-job_name job_name]
[-submit_timeout timeout]
[-run_timeout timeout
 | -run_timeout_factor factor]
[-queue queue_name]
[-var_list name_value_pairs]
[-job_script script_path]
-batch_script script_path
-exec exec_path
[job_name_list]
[-verbose]
```

Data Types for Submitting a Job

<i>num_jobs</i>	int or "all"
<i>stage_name_list</i>	string list
<i>job_name</i>	string[:dependencies]
<i>timeout</i>	time
<i>factor</i>	int
<i>queue_name</i>	string
<i>name_value_pairs</i>	string list
<i>script_path</i>	string
<i>exec_path</i>	string
<i>job_name_list</i>	string list

SYNTAX for Killing a Job

```
status run_parallel_jobs

[-kill]
[job_name_list]
[-verbose]
```

SYNTAX for Checking Job Status

```
status run_parallel_jobs

[-check]
[job_name_list]
[-verbose]
[-temp_dir string]
```

`[-create_scripts_only]`

ARGUMENTS

`-serial`

Causes the jobs to be run serially rather than in parallel.
This option is rarely used. When used, it is almost always used for debugging flows.
This option and the **-parallel** option are mutually exclusive; you can specify only one. If you specify neither option, there is no limit to the number of jobs run and all jobs are launched at the same time.

`-parallel num_jobs`

Controls the level of parallelism used for job submission.
You can restrict the number of active jobs to a specified number based on machine or license resource restrictions. You can also specify **all**, in which case all jobs are launched in parallel.
This option and the **-serial** option are mutually exclusive; you can specify only one. If you specify neither option, there is no limit to the number of jobs run and all jobs are launched at the same time.

`-stage_names stage_name_list`

Specifies the stage names for which status information is returned from the child processes. The stages are displayed in the GUI. This option is not needed unless the GUI is used.
When no stages are defined, a single stage called "Job Status" is defined for each running job and is used to collect updated status information.

`-job_name job_name`

Specifies the name of the job set. This name is used for the job set within the queuing system and for the title bar if you open the GUI.

`-submit_timeout timeout`

Specifies the timeout value in the following format: [[HH:]MM:]SS[.SS]. For example, if you specify **-submit_timeout 30**, this means 30 seconds. If you specify **-submit_timeout 2:30**, this means 2 minutes and 30 seconds. If you specify hours, the maximum number of minutes is 59; otherwise, you can specify any number of minutes. If you specify minutes, the maximum number of seconds is 59; otherwise, you can specify any number of seconds.
If the submitted jobs do not become running jobs within the specified timeout, they are killed. This is to prevent hanging jobs in the queuing system.
If you do not specify this option, the system waits as long as needed for jobs to start.

`-run_timeout timeout`

Specifies the maximum amount of elapsed time that a job can run in the following format: [[HH:]MM:]SS[.SS]. For example, if you specify **-run_timeout 30**, this means 30 seconds. If you specify **-run_timeout 2:30**, this means 2 minutes and 30 seconds. If you specify hours, the maximum number of minutes is 59; otherwise, you can specify any number of minutes. If you specify minutes, the maximum number of seconds is 59; otherwise, you can specify any number of seconds.

If the elapsed time exceeds this amount, the job is killed. You can use this option to prevent stuck or runaway jobs that will prevent a flow from running

to completion.

This option and the **-run_timeout_factor** option are mutually exclusive; you can specify only one. If you specify neither, there is no time limit.

-run_timeout_factor factor

Specifies a factor used to determine the maximum elapsed time that a job can run. The factor value must be greater than one. The factor relates to the average elapsed time of completed jobs. When one or more jobs have finished successfully, an average elapsed time of completion is computed. When a job's elapsed time rises above this average times the *factor*, the job is killed. The expectation is that in most cases, the parallel jobs are arranged so that they run for approximately the same time. By setting a *factor* in the range of 5-10, you can effectively kill runaway jobs without fear of killing a long-running job that will ultimately succeed.

This option and the **-run_timeout** option are mutually exclusive; you can specify only one. If you specify neither, there is no time limit.

-queue queue_name

Specifies the queue name in which to run the jobs. This name has meaning only to a given installation using the job script specified by the **-job_script** option.

In the default job script (which ties to LSF), the default queue name is amd64.

-var_list name_value_pairs

Communicates information from the parent to the child processes. The values in this list are specified as pairs of the form *name=value*. The *name* values become UNIX environment variables that are passed through the queuing system to the child jobs.

In addition to the variables and values specified in this list, there are several predefined variables managed by the command. The HostName and PortNum variables are set to the parent host and the number of the port on which the parent will be listening for child status information, which is communicated back to the parent through the **send_flow_status** command. The JobName variable contains the name of the job and is available to the child processes. You must use this option to pass through any additional data that is needed by the batch script given to the executable.

-job_script script_path

Specifies the path to the job submission script.

The default job submission script is located at \$root/auxx/syn/chipopt/job_run.pl. This default job submission script interfaces to LSF and provides a set of capabilities that is sufficient for many, if not most, users.

You can also construct your own job submission script. The script can be in any language, as long as it is directly executable by the system. Using this mechanism, you can interface to any job-control system, proprietary or commercial.

The job submission script must use the following syntax:

```
job_id_list your_script_here
-submit
[-queue queue_name]
[-wait]
[-verbose]
[-var_list name_value_pairs]
-script script_path
```

```
-exec exec_path  
-temp_dir temp_dir  
job_name_list
```

With the exception of the job_id_list return value, the definitions for the options and arguments is the same as for the **run_parallel_jobs** command. The job_id_list value is a single string listing the submitted jobs in the form "JOB_NAME_1:JOB_ID_1 JOB_NAME_2:JOB_ID_2 ...", where the JOB_NAME values come from the *job_name_list*, and the JOB_ID values come from the queuing system. The JOB_ID values are unique values returned as the result of the job submission. These values are used to identify jobs when using the kill or check modes.

```
-batch_script script_path
```

Specifies the path to the batch script that is supplied to the executable. The batch script can contain any commands and is passed to the executable by using the **-f script_path** option.

```
-exec exec_path
```

Specifies the path to the executable that is run in parallel. It has available to it the variables passed through the UNIX environment defined in the **-var_list** option above as well as the batch script defined in the **-batch_script** option and passed to the executable on the command line by using the **-f script_path** syntax.

```
job_name_list
```

Specifies a list of names for the jobs. These names have meaning only when taken together with the batch script and executable that are launched in parallel. For many cases, they are the names of subblocks in a hierarchical design, but they can refer to any task that can benefit from parallel execution.

This argument is required when submitting jobs and optional when killing or checking jobs. If you do not specify this argument when killing or checking jobs, all running jobs are processed.

If dependencies among jobs exist, you can specify them by using a special syntax in the *job_name_list* argument. For each job, you can specify a comma-separated list of jobs that must complete before this job is launched. A semicolon separates the job name from its associated dependency list. For example, to run jobs A and B in parallel and then run job C only when both jobs A and B have successfully completed, enter the following command: is:

prompt> **run_parallel_jobs A B C:A,B** In this example, if either job A or B fails, job C is skipped.

If you do not specify any dependencies, none are assumed and the jobs run in parallel up to the level of parallelism currently in effect.

```
-verbose
```

Prints additional status information. This option is usually used while debugging the logistics of running a new flow.

```
-kill
```

Kills the specified jobs that are still running.

It is possible for a job to complete between the time the kill order goes out and when the time the queuing system can kill the job. In this case, an EOF status message will probably be received from the child. This means that you might observe in the GUI a job turning red as it is killed, only to have it turn purple as an EOF status is received from the child.

Because the batch version of **run_parallel_jobs** blocks until the children are finished, this option can be used only when the job submission mode of the command is run in GUI mode.

-check

Checks the specified jobs that are still running.

By default, the **run_parallel_jobs** command checks on the running children once a minute. You can use this option to accelerate this checking.

Because the batch version of **run_parallel_jobs** blocks until the children are finished, this option can be used only when the job submission mode of the command is run in GUI mode.

DESCRIPTION

This command has three syntax modes: submit, kill, and check.

The first and most complex mode submits jobs. To submit a job, you must specify at least **-batch_script**, which is the script that is provided to the child jobs; **-exec**, which is the path to the executable that is run for the child jobs; and a list of named jobs. In this case, a job is launched for each named job of the specified executable using the specified batch script. Status is collected about the progress of each job, and the **run_parallel_jobs** command completes after the final job has finished.

From this basic syntax, there are many increasing levels of complexity. You can invoke a GUI and define a set of stages for the child flows. The GUI visually records the progress of the child jobs through the stages from status information communicated back from the children. You can add a job name to this run, which labels the information and keeps it separate from other jobs that might be run in the same parent session. You can set up a series of timeouts that prevent the command from hanging in the event that the queuing system hangs or if one or more of the child jobs hangs or is stuck in a single stage. You can provide a customized job script to control the interface to the queuing system. You can pass to the child jobs an arbitrary set of variable data values that can customize the behavior of the batch script.

In the second mode of the command, you can kill (stop) running jobs. In this mode, you specify the names for the jobs of interest. If any of the specified jobs are still running, they are killed using the queuing system commands. If you don't specify any job names, all running jobs are killed.

In the final mode of the command, you can check on the status of running jobs. Normally this is not necessary, as the command checks on the status of remaining jobs once a minute. This means that any job failure or loss of communication with the child is detected within a minute. You can use the **-check** option to accelerate this process if desired. Also, there is no way to detect that a job has been launched from the job queue, so until the first status message is received from the child job, the status is vague. You can use the **-check** option to detect children who are now active.

By design, this command is independent of the batch script or the child-job executable. The definitions of stages, definitions of variables, the contents of the batch script, the choice of executable, and the names for the jobs are entirely up to you. You decide what the meaning of the pieces is based upon your own conventions

and needs. This makes **run_parallel_jobs** a general-purpose command that can find use anywhere a set of tasks can be run in parallel.

EXAMPLES

This example launches jobs to implement subblocks in a hierarchical design:

```
prompt> run_parallel_jobs -batch_script block_flow.tcl -exec icc \
-gui -stage_names "Init PlaceOpt ClockOpt RouteOpt ModelCreation" \
-var_list MWLibName=orca.mw BLENDER_0 BLENDER_1 BLENDER_2 BLENDER_3 BLENDER_4
```

This example sets a variable MWLibName to orca.mw. This variable gets passed to the five jobs for the blocks BLENDER_0 through BLENDER_4 to the icc executable using the batch flow script block_flow.tcl. This script includes **send_flow_status** commands to send status back to the parent process. Because the example uses the **-gui** option, there is a GUI display of the status of each stage for each of the five jobs while they are executing. After the last job has finished, the command returns. It returns a true status if all jobs have succeeded and a false status if one or more of the child jobs have failed.

SEE ALSO

[send_flow_status\(2\)](#)

run_signoff

Performs signoff analysis by invoking PrimeTime and Star-RCXT.

SYNTAX

```
status run_signoff
[-check_only]
[-incremental]
[-signoff_analysis true | false | sleep | wakeup]
[-aocvm]
[-path_based_analysis]
[-variation]
[-keep_license]
[-snapshot base_name]
[-correlation {setup spef_out}]
```

ARGUMENTS

-check_only
Performs consistency checking only without actually invoking Star-RCXT or PrimeTime.

-incremental
Performs incremental signoff analysis instead of full signoff analysis. In order to perform incremental signoff analysis, a full signoff analysis must have been done already.

-signoff_analysis true | false | sleep | wakeup
Enables or disables signoff analysis mode with true|false. The default is true. If you are in signoff mode, use *sleep* to enter the sleep mode by releasing all PrimeTime processes. If you are in sleep mode, use *wakeup* to re-acquire all PrimeTime processes.

-aocvm
Indicates that the timing paths are to be adjusted using Advanced On-Chip Variation Modeling (AOCVM) information. AOCVM computes the effects of OCV on timing using variable derate factors that consider the location and the logic depth of each path being analyzed. This approach reduces pessimism compared to global derating, thereby minimizing unnecessary over-design.

-path_based_analysis
Enables path-based analysis capability in PrimeTime.

-variation
Indicates that Star-RCXT VX and PrimeTime VX are invoked to perform variation aware analysis.

-keep_license
Retains IC Compiler licenses while running signoff tools.

-snapshot *base_name*
Enables snapshot. **run_signoff** saves a design after each invocation, using the

given *base_name*, appended with an index. **run_signoff** also saves a session from PrimeTime, using the given *base_name*, appended with an index.

-correlation {setup spef_out}

Performs correlation checking between IC Compiler and Star-RCXT and/or between IC Compiler and PrimeTime with **run_signoff**.

- **setup:** Checks IC Compiler, PrimeTime and Star-RCXT settings and reports any inconsistency if any. In addition, a script called *ICC.tcl* will also be generated to correct the inconsistent settings. For a multicorner-multimode (MCMM) design, the command will generate reports and scripts for each scenario.

When analysis is complete, exit the signoff mode by running **run_signoff -signoff_analysis false** and source the script before running the signoff driven design closure flow.

- **spef_out:** Generates two parasitic files in the SPEF format, one from IC Compiler per corner and one from Star-RCXT per scenario. A sample script called *run_myBingo.csh* will also be generated to run the myBingo utility for SPEF files comparison and parasitics correlation checking between IC Compiler and Star-RCXT. It is recommended that you check the sample script and modify it accordingly to match the design technology.

All files generated during correlation will be saved in a directory named *correlation_report.<time_stamp>*. This report directory will be created automatically in each correlation run.

DESCRIPTION

The **run_signoff** command performs signoff analysis by invoking signoff tools: PrimeTime and Star-RCXT. Star-RCXT provides signoff quality parasitic extraction; PrimeTime provides signoff quality timing and SI analysis. Use **set_primestime_options** and **set_starrcxt_options** to customize setting for the **run_signoff** run.

To enable SI analysis, use the **set_si_options** command.

run_signoff does not perform optimization. Use **signoff_opt** to perform signoff costing based optimization.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following example runs the **run_signoff** command. Running the **report_timing** command after **run_signoff** will report PrimeTime timing based on Star-RCXT extraction.

```
prompt> open_mw_cel -lib my_lib my_cel
prompt> set_primestime_options -exec_dir /PrimeTime/linux/syn/bin
prompt> set_starrcxt_options -exec_dir /StarRCXT/linux/bin -max_nxtgrd_file /design/max.nxtgrd -map_file /design/map_file
```

```
prompt> run_signoff  
prompt> report_timing
```

The following example runs the **run_signoff** command with the *-correlation* option. A correlation report and a script called *ICC.tcl* will also be generated.

```
prompt> run_signoff -correlation {setup}
```

The following example runs the **run_signoff** command with the *-correlation* option by generating two SPEF files from IC Compiler and Star-Rcxt and one script file for running myBingo.

```
prompt>run_signoff -correlation {spef_out}
```

SEE ALSO

```

save_mw_cel

Saves the specified design in Milkyway format.

SYNTAX

```
status save_mw_cel
[-as name]
[-increase_version]
[-scenarios scenario_list]
[-hierarchy]
[-previous]
[-check_only]
design_name
[-overwrite]
```

Data Types

<i>name</i>	string
<i>scenario_list</i>	list
<i>design_name</i>	string

ARGUMENTS

-as *name*

Saves the specified design as a Milkyway design with the specified name. This can be a brand new Milkyway design or an existed Milkyway design. If it is an existed Milkyway design, it can be similar to the name of the design to be saved and the data will be saved to the same design, or else it must not open yet.

The name can be formatted as A[.B], in which the string A represents the base name of the design and the string B represents the view name of the design. Currently, 4 kinds of views are supported: CEL, FRAM, err, and FILL. You can not specify the mw_cel of other views through the option. Please refer to the man page of mw_cel_collection for how to specify a valid Milkyway design name. save_mw_cel runs database consistency checker internally. If it fails, _CORRUPT will be appended to the Milkyway design name. For example, if you specify the name as "abc.CEL" and CEL-checker fails before saving the design, the Milkyway design name is "abc_CORRUPT" and is created in the CEL view. This option can not be used with **-hierarchy** option.

-increase_version

Increases the version of the Milkyway design to be saved. If this option is not specified, it will overwrite current version of specified Milkyway design. If used with **-as** option, it means to increase the version of Milkyway design specified in as option.

If database consistency checker fails, _CORRUPT will be appended to the Milkyway design name.

-scenarios *scenario_list*

Specifies a list of scenarios whose constraints are saved with the Milkyway design. By default, the command includes all scenarios.

-hierarchy
Saves the modified top-level Milkyway design, its modified subdesigns, and all attached files. The saved data will overwrite current version of the designs.
The subdesigns must be in the same design library as the top-level Milkyway design. Subdesigns (modified or unmodified) that are instantiated from the reference libraries are not touched.
Note: This option can not be used with the **-as** or **-increase_version** option.

-previous
If current cell's data model version is the latest, convert it back to previous version and save. If the cell has been modified after opening, the user must use "save_mw_cel" to save the cell to disk first, then use "save_mw_cel -previous -as" to save it to the previous version. Otherwise, "save_mw_cel -previous -as" will not be allowed. After saving, current cell will be closed. If the user wants to continue operating on the cell, the user must re-open it. This option must be used together with **-as** or **-increase_version** option to avoid overwriting.

-check_only
Prints the list of Milkyway designs to be saved, but does not execute the save operation. If you use this option, you must also use the **-hierarchy** option.

design_name
Specifies the Milkyway design to be saved. By default, the command saves the current Milkyway design. If database consistency checker fails, _CORRUPT will be appended to the Milkyway design name.

DESCRIPTION

This command saves the specified design in Milkyway format. The open status of all Milkyway designs in current session are not affected.

When use the **-as** option, this command saves the specified design as a new design and copies the attach files for the new design. The associated views will be copied in overwrite mode, when the view name of the saved design is **CEL** and the character . (period) is not specified in the name of the new design.

The **-increase_version** option increases the version of the design to be saved as and copies all the attach files. Combine the **-as** option with **-increase_version**, the command increases the versions of the associated views, when the view name of the saved design is **CEL** and the character . (period) is not specified in the name of the design to be saved as.

Database consistency checker will be run before saving the Milkyway design. If it fails, _CORRUPT will be appended to the Milkyway design name.

To save the Milkyway design hierarchically, use the **-hierarchy** option. When the command finishes saving the Milkyway design, it prints the names of the saved Milkyway designs.

The command saves the top-level Milkyway design or subdesigns when they have been modified. When the top-level Milkyway design is un-modified while subdesigns are

modified, the command saves the modified subdesigns and updates the time stamp of the top-level Milkyway design.

The **-hierarchy** option does not close any Milkyway designs. Thus, any open Milkyway designs remain open after the hierarchical save. If you do another hierarchical save, the whole process is applied again for the specified top-level Milkyway design.

The **-previous** option can only convert current cell from the latest schema version to the previous one, it cannot convert cell with older schema version. And if current cell has child referenced cells, this option cannot convert these child cells, instead it will error out.

When you use the **-check_only** option together with the **-hierarchy** option, the command prints the list of Milkyway designs to be saved, but does not save the Milkyway designs.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example saves the current design as a Milkyway design named *new*.

```
prompt> save_mw_cel -as new
Information: Performing CEL netlist consistency check. (MWDC-118)
Information: CEL consistency check PASSED. (MWDC-119)
Information: Saved design named new. (UIG-5)
1
```

The following example saves the current design as a Milkyway design named *new_CORRUPT*.

```
prompt> save_mw_cel -as new
Information: Performing CEL netlist consistency check. (MWDC-118)
Error: Cell UPC_BLK (0xa0b) reachable from parent hierarchy alu (0xa01) multiple times. (MWDC-131)
Error: CEL consistency check FAILED (MWDC-100)
Information: Saved design named new_CORRUPT . (UIG-5)
1
```

The following example saves the *ORCA* design and the designs in its hierarchy.

```
prompt> save_mw_cel -hierarchy ORCA
Starting hierarchical save ...
Saving the cell: BLENDER_4.CEL;1 ...
Saving the cell: BLENDER_1.CEL;1 ...
Saving the cell: BLENDER_3.CEL;1 ...
Saving the cell: BLENDER_0.CEL;1 ...
```

```
Saving the cell: ORCA.CEL;1 ...
Information: Saved design named ORCA.CEL;1. (UIG-5)
1
```

The following example checks and finds the sub-design *BLENDER_0* is modified, then saves the *BLENDER_0* design and its top-level design *ORCA*.

```
prompt> save_mw_cel -hierarchy -check
Starting hierarchical save with check only enabled ...
check only -- will save the cell: BLENDER_0.CEL;1 ...
Information: Saved design named ORCA.CEL;1. (UIG-5)
1
prompt> save_mw_cel -hierarchy
Starting hierarchical save ...
Saving the cell: BLENDER_0.CEL;1 ...
Saving the cell: ORCA.CEL;1 ...
Information: Saved design named ORCA.CEL;1. (UIG-5)
1
```

```

save_qtm_model

Saves the current Quick Timing Model (QTM) description.

SYNTAX

```
string save_qtm_model
```

ARGUMENTS

The **save_qtm_model** command has no arguments.

DESCRIPTION

This command creates an in-memory DB timing model for the QTM model and indicates to ICC Design Planning that the model being defined is completed. All QTM commands must be placed between a **create_qtm_model** and a **save_qtm_model** command.

This command creates an in-memory Synopsys .db representation to be used by the ICC Timer. This command runs faster than **write_qtm_model** and doesn't require disk I/O. This command may be called multiple times in an ICC session, if the user tweaks the QTM model.

To display information about the current QTM model, use the **report_qtm_model** command.

For a basic description about QTM, see the **create_qtm_model** manual page. For a more detailed description about QTM, see the *ICC Design Planning User Guide*.

The command line options "-format format_list", "-output file_name" and -library_cell for **save_qtm_model** command are redundant and maintained for backward compatibility with JupiterXT and PrimeTime.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example creates in-memory DB timing model for QTM model.

```
prompt> save_qtm_model -format {db lib}
```

The following example creates in-memory DB timing model for QTM model.

```
prompt> save_qtm_model
```

SEE ALSO

`create_qtm_model(2)`
`report_qtm_model(2)`

`save_qtm_model`
2090

save_upf

Writes out the UPF commands in the specified file. This command is supported only in UPF mode.

SYNTAX

```
collection save_upf
upf_file_name
```

Data Types

upf_file_name string

ARGUMENTS

upf_file_name

Specifies the name of the file to which UPF commands are to be written out.

DESCRIPTION

This command writes out the UPF that is currently part of the design to the specified file. This UPF is basically what you have loaded by using the **load_upf** command or the command line and the changes made to it during optimization and UPF commands specified at the command prompt in that session. For example if the optimization has changed the name of the cell that drives and isolation signal, it will modify the set_isolation_control to reflect the new isolation_signal name.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> save_upf
```

SEE ALSO

select_mim_master_instance

SYNTAX

```
status select_mim_master_instance
plan_group
```

Data Types

plan_group collection of plan groups

ARGUMENTS

plan_group

Collection of plan groups to identify as the "master" plan group among a MIM group of plan groups. This collection should contain only plan groups which belong to MIM groups of plan groups, and for each MIM group of plan groups only 1 plan group each MIM group should be present in the collection.

DESCRIPTION

This command specifies a plan group as the "master" plan group among a set of plan groups that has been previously grouped by the "uniquify_fp_mw_cel - store_mim_property" command. That command will create MIM groups which are identifiable by the application as sharing a common hierarchical reference cell. A MIM group is a set of plan groups that possess a common database property that associates the plan groups with each other, and which identifies the name of the hierarchical cell instance reference. When a MIM group of plan groups exists with this common property, commit_fp_plan_groups must identify one plan group among this MIM group of plan groups as the "master" plan group. commit_fp_plan_groups will then only create a cell view once for the plan group determined as the "master" plan group. The user, then, may specify which plan group among a MIM group to be identified as the "master" plan group. This command allows the user to specify which plan group within a MIM group that the commit_fp_plan_groups command should treat as the "master" plan group. (If a "master" has not been specified, commit_fp_plan_groups will randomly assign one of the plan groups as the "master").

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies a particular plan group as the "master" of it's MIM group:

```
prompt> select_mim_master_instance [get_cells {planGroupA}]
```

SEE ALSO

[commit_fp_plan_groups\(2\)](#)

send_flow_status

Sends flow status from a running job to its parent. It is used exclusively with the **run_parallel_jobs** command.

SYNTAX

```
status send_flow_status
[-job_name job_name]
[-host host_name]
[-port port_number]
-stage_name stage_name
-status current_status
[-eof]
[-verbose]
```

Data Types

<i>job_name</i>	string
<i>host_name</i>	string
<i>port_number</i>	int
<i>stage_name</i>	string
<i>current_status</i>	one of Running, Succeeded, or Failed

ARGUMENTS

-job_name *job_name*

Specifies the name for the current job.
If you do not specify this option, the command checks the JobName UNIX environment variable. If neither is set, the command fails.

-host *host_name*

Specifies the host name for the parent of the current job.
If you do not specify this option, the command checks the HostName UNIX environment variable. If neither is set, the command fails.

-port *port_number*

Specifies the port number for the parent of the current job.
If you do not specify this option, the command checks the PortNum UNIX environment variable. If neither is set, the command fails.

-stage_name *stage_name*

Specifies the name of the current stage. This is a required option.
Stage names are arbitrary and have meaning only to the **run_parallel_jobs** command and the child jobs that use **send_flow_status** to communicate flow status back to the parent. The stage names **must** be consistent between the child and parent. If a stage name is used in a **send_flow_status** call that is not known to the parent job, a warning message is generated in the parent. If a stage name is used by the parent but not used in the child, the named stage will appear to be "skipped" in the parent (since no information will ever be reported on that stage by the child).

```

-status current_status
    Reports the status back to the parent. This is a required option.
    There are many status values, but the only ones that make sense coming from
    a child are Running (when the stage is starting) and then one of Succeeded
    or Failed (when the stage is over).

-eof
    Indicates to the parent that this job has completed and will be exiting soon.
    This option is used to improve the latency in detecting job completion. This
    option should only be used right before an exit. If any processing takes place
    after this option is used but before the child process exits, it creates a
    flow that is intermittently error-prone.

-verbose
    Generates detailed information about communication with the parent.
    This option is used only for debugging when setting up a flow. After a flow
    is working correctly, it is not needed.

```

DESCRIPTION

This command sends status information back from a child job launched through the **run_parallel_jobs** command back to the parent job. The command must have the job name for the child and the host name and parent number of the parent process. This information can be specified on the command line or it can come from the UNIX environment. Because the **run_parallel_jobs** command sets these values, you should never need to set them. The only information you need to provide is the current stage name (set up by convention between the **run_parallel_jobs** command in the parent and the batch script being used in the child) and the actual status. Status values are predefined, and the only ones that make sense in this context are **Running**, **Succeeded**, and **Failed**. The **-eof** option is provided to let the parent know that the child process has finished its flow and will be exiting (to reduce the latency in the parent process in determining when the child exits). The **-verbose** option is provided for use when setting up and debugging a flow.

EXAMPLES

The following example sends status in the briefest form:

```

prompt> send_flow_status -stage PlaceOpt -status Succeeded
1

```

The following example sends status using all the options:

```

prompt> send_flow_status -job_name BLOCK_1 -host_name ada \
-port_num 4523 -stage RouteOpt -status Succeeded -eof
1

```

set_active_scenarios

Specifies which scenarios are to be active.

SYNTAX

```
int set_active_scenarios  
scenario_list | -all
```

Data Types

scenario_list list of strings

ARGUMENTS

scenario_list
 Specifies which scenarios are active.
 This argument and the **-all** option are mutually exclusive; specify only one.

-all
 Makes all scenarios active.
 This option and the *scenario_list* argument are mutually exclusive; specify only one.

DESCRIPTION

Specifies which scenarios are active.

To report timing results with back-annotated delays for newly activated scenarios, run **extract_rc -estimate** before issuing **report_timing** command.

Multicorner-Multimode Support

This command uses information from both active and inactive scenarios.

EXAMPLES

The following example uses **set_active_scenarios** to set only one scenario active.

```
prompt> create_scenario MODE1  
prompt> create_scenario MODE2  
prompt> set_active_scenarios {MODE1}  
prompt> all_scenarios  
MODE1 MODE2  
prompt> all_active_scenarios  
MODE1
```

SEE ALSO

current_scenario(2)
remove_scenario(2)
create_scenario(2)
extract_rc(2)
```

set_ahfs_options

Specifies the options to be used when running automatic high-fanout synthesis (AHFS) .

SYNTAX

```
status set_ahfs_options
[-optimize_buffer_trees true | false]
[-skip_for_hfs pins_or_ports]
[-enable_port_punching true | false]
[-no_port_punching cells]
[-default_reference references]
[-port_map_file file_name]
[-preserve_boundary_phase true | false]
[-constant_nets true | false]
[-hf_threshold integer]
[-mf_threshold integer]
[-remove_effort none | medium | high]
[-default]
```

Data Types

<i>pins_or_ports</i>	collection
<i>cells</i>	string
<i>references</i>	string
<i>file_name</i>	string

ARGUMENTS

-optimize_buffer_trees true | false

Controls whether automatic high-fanout synthesis uses the enhanced optimization algorithm to create buffer trees.

By default, this option is true and automatic high-fanout synthesis optimizes the buffer trees, including automatic analysis and removal of some buffer and inverter trees and resynthesis, as needed for better QoR. The enhanced algorithm is also aware of more design constraints, which often leads to reduced congestion better timing QoR.

If the design contains buffer trees that should not be modified in any way during automatic high-fanout net synthesis, use the **-skip_for_hfs** option to identify these trees. This option prevents modification of the specified buffer trees during **create_buffer_tree**, **remove_buffer_tree**, and the high-fanout synthesis phase of **place_opt**.

When **-optimize_buffer_trees** is true, the following options are ignored: **-hf_threshold**, **-mf_threshold**, **-remove_effort**.

When set to false, automatic high-fanout synthesis uses the original algorithm to insert buffer or inverter trees as needed for high-fanout synthesis. The removal of buffer trees is controlled separately by the **-remove_effort** option and the **remove_buffer_tree** command.

-skip_for_hfs *pins_or_ports*

Specifies the drivers of buffer trees that are not to be modified during automatic high-fanout synthesis. The drivers must be output pins on leaf

cells or input ports. This option is relevant only when -**optimize_buffer_trees** is true.
This option prevents modification of the specified buffer trees during **create_buffer_tree**, **remove_buffer_tree**, and the high-fanout synthesis phase of **place_opt**. It has no effect on the optimization phases of other commands, such as **psynopt**.

-enable_port_punching true | false

Enables or disables port punching in automatic high-fanout synthesis optimization. The default is true.

When this option is true, automatic high-fanout synthesis can insert buffers or inverters across hierarchy boundaries to get better QoR.

You can use the **-no_port_punching** option to prevent port punching on specific hierarchical cells, even when **-enable_port_punching** is true.

-no_port_punching cells

Specifies the hierarchical cells for which automatic high-fanout synthesis cannot add or remove any ports. The cells are specified as a string of hierarchical cell instance names separated by commas, such as "sub/mod1 sub/block2".

You can use this option to limit the port punching on specific hierarchical cell instances when **-enable_port_punching** is true (the default). If **-enable_port_punching** is false, there is no need for this option.

During the removal phase of automatic high-fanout synthesis, inverters might be moved across hierarchical boundaries to cancel "inverter chains" for better QoR. If you do not want to allow any phase changes on hierarchical boundaries, use the **-preserve_boundary_phase true** option instead of using this option.

-default_reference references

Specifies a list of buffers or a list of inverters for automatic high-fanout synthesis to use when constructing new buffer or inverter trees. The list must be either entirely buffers or entirely inverters, not a mixture of buffers and inverters.

You can specify the reference cells with or without the library prefix. If you do not specify this option, or if the specified references are not active buffer cells, automatic high-fanout synthesis tries to use all active buffer or inverter cells defined in the library.

When **-optimize_buffer_trees** is true and the list contains buffers, automatic high-fanout synthesis automatically uses inverters as needed to construct logically correct buffer and inverter trees.

-port_map_file file_name

Specifies the name of the port mapping file. This option is used only when **-enable_port_punching** is set to true.

If you do not specify this option and **-enable_port_punching** is set to true, the default name of the port mapping file is <design_name>.port_map.<version>. The initial file is created with a version of 0. If the specified port mapping file already exists, a new version of the file is created with the version number increased by one, such as <design_name>.port_map.1.

-preserve_boundary_phase true | false

Specifies whether automatic high-fanout synthesis is allowed to move inverters across hierarchical boundaries so that the logical phase of the

boundary changes.

The default is false, meaning that automatic high-fanout synthesis can freely move inverters across hierarchical boundaries. This default behavior often leads to better QOR because automatic high-fanout synthesis can move inverters and cancel inverter chains as needed.

-constant_nets true | false

Specifies that automatic high-fanout synthesis should work on constant nets as well as signal nets.

By default, automatic high-fanout synthesis ignores constant nets.

-hf_threshold integer

Specifies the fanout threshold for high-fanout optimization during automatic high-fanout synthesis.

The default value is 100.

The tool performs maximum-fanout-driven high-fanout optimization on the nets in your design that have fanout greater than or equal to the threshold value you set for this option, after coarse placement and before normal optimization. If you set the threshold for this option as less than or equal to 0, the tool does not process any of the nets.

When **-optimize_buffer_trees** is true, this option is ignored.

-mf_threshold integer

Specifies the fanout threshold for medium-fanout optimization during automatic high-fanout synthesis. The default value is -1.

The tool performs timing-driven medium-fanout optimization on the nets in your design that have fanout greater than or equal to the threshold value you set for this option, after coarse placement and before normal optimization. If you set the threshold for this option as less than or equal to 0, the tool does not process any of the nets.

If you set the threshold for this option equal to or more than the value you specified for the **-hf_threshold** option, this optimization is not enabled.

When **-optimize_buffer_trees** is true, this option is ignored.

-remove_effort none | medium | high

Specifies the effort level for removing existing buffer trees or inverter trees during automatic high-fanout synthesis.

The default value is none.

Automatic high-fanout synthesis removes existing buffer trees or inverter trees in your design, after coarse placement and before normal optimization, guided by the value you set for this option.

The accepted values are as follows:

* **none** (the default)

Indicates that the tool does not remove any buffer trees or inverter trees.

* **medium**

Indicates that the tool removes buffer trees or inverter trees that have negative maximum delay slack.

* **high**

Indicates that the tool removes all buffer trees and inverter trees.

When **-optimize_buffer_trees** is true, this option is ignored.

```
-default
    Resets all of the options set by previous set_ahfs_options commands to their
    default values.
```

DESCRIPTION

This command defines the constraints used while performing automatic high-fanout optimization.

You can report the settings by running the **report_ahfs_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to set automatic high-fanout synthesis options for current design. It sets the high-fanout optimization threshold to 50, turns off the medium-fanout optimization, enables port punching, sets the buffer removal effort to remove only buffer tree with a negative maximum delay slack, and uses cells of type BUFX3M or ss_0v80_125c/DLY4X4M during high-fanout synthesis. The **-preserve_boundary_phase false** option indicates that inverters should not move across hierarchical boundaries. The **-no_port_punching "sub/mod1 sub/mod2"** option indicates that the sub/mod1 and sub/mod2 hierarchical cells should have no changes to their ports during automatic high-fanout synthesis. The report indicates that the **-skip_for_hfs** option is ignored when **-optimize_buffer_trees** is false.

```
prompt> set_ahfs_options \
        -optimize_buffer_trees false \
        -hf_threshold 50 \
        -mf_threshold -1 \
        -enable_port_punching true \
        -remove_effort medium \
        -no_port_punching "sub/mod1 sub/mod2" \
        -preserve_boundary_phase false \
        -default_reference "BUFX3M ss_0v80_125c/DLY4X4M"
prompt> report_ahfs_options
Report AHFS options:
*****
AHFS options for the design:
  Enable port punching: ON
  Default Reference : BUFX3M ss_0v80_125c/DLY4X4M
  Port Map File :
  Preserve Boundary Phase : OFF
  No Port Punching on these hier cells : "sub/mod1 sub/mod2"
  Constant Nets allowed during AHFS optimization : OFF
  -optimize_buffer_trees FALSE
    High-fanout(HF) threshold: 50
    Medium-fanout(MF) threshold: -1
    Remove effort: medium
    Ignoring: -skip_for_hfs
```

The following example shows how to use the **-optimize_buffer_trees** option to activate optimization of buffer and inverter trees, including automatic analysis and removal of some trees, and resynthesis to achieve better QoR. The report indicates that the **-hf_threshold**, **-mf_threshold**, and **-remove_effort** options are ignored when **-optimize_buffer_trees** is true. The buffer tree driven by the u_start/gte_107/U151/Y leaf pin is protected from automatic high-fanout synthesis optimization during **create_buffer_tree** and **remove_buffer_tree**.

```
prompt> set_ahfs_options \
    -optimize_buffer_trees true \
    -skip_for_hfs [get_pin u_start/gte_107/U151/Y]
prompt> report_ahfs_options
Report AHFS options:
*****
AHFS options for the design:

set_always_on_strategy

Sets the always-on strategy for shutdown power domains.

SYNTAX

```
status set_always_on_strategy
-object_list list_of_domains
-cell_type single_power | dual_power
```

Data Types

list_of_domains collection

ARGUMENTS

```
-object_list list_of_domains
    Specifies one or more power domains for which to define the always on
    strategy.

-cell_type single_power | dual_power
    Specifies the type of always_on cells to be used; either single power cells
    or dual power cells with backup power. The default is dual_power.
```

DESCRIPTION

This command is used to set the always_on strategy for shut-down power domains. The strategy indicates the type of cells that are to be used for always-on buffering. You can choose to use standard cells with single power cells as AO or dual power cells with backup supply. This information drives the cell selection of the optimizations.

Use dual power cells for always-on if you want to route backup power to these cells. Use single power cells as always-on if you are reserving special sites for these cells in the floorplan.

This command ensures that the specified *list_of_domains* consists of power domains that are defined as power down.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLE

The following example sets the always-on strategy on "switchable_domain" to use single power standard cells.

```
prompt> set_always_on_strategy\
```

```
-object_list switchable_domain\  
-cell_type single_power  
1
```

SEE ALSO

report_power_domain(2)  
report_power_guide(2)  
set_power_guide(2)  
unset_power_guide(2)
```

set_annotated_check

Sets the setup, hold, recovery, or removal timing check value between two pins.

SYNTAX

```
int set_annotated_check
check_value
-from from_pins
-to to_pins
-setup
| -hold
| -recovery
| -removal
| -nochange_high
| -nochange_low
[-rise | -fall]
[-clock clock_check]
[-worst]
```

Data Types

<i>check_value</i>	float
<i>from_pins</i>	list
<i>to_pins</i>	list

ARGUMENTS

check_value
Specifies the timing check value between pins on the same cell. You must express *check_value* in units consistent with the technology library used during optimization. For example, if the technology library specifies delay values in nanoseconds, *check_value* must be expressed in nanoseconds: *check_value* can be negative.

-*from from_pins*
Specifies a list of leaf cell clock pins that are the startpoints of the timing arcs for which checks are to be annotated.

-*to to_pins*
Specifies a list of leaf cell data pins that are the endpoints of the timing arcs for which checks are to be annotated.

-*setup* | -*hold* | -*recovery* | -*removal* | -*nochange_high* | -*nochange_low*
Specifies the type of the timing check. There must be a corresponding timing arc between the *from* and *to* pins.
The **-setup** option indicates that data must be stable for the amount of time specified by *check_value* before the closing clock edge.
The **-hold** indicates that data must be stable for the amount of time specified by *check_value* after the closing clock edge.
The **-recovery** option indicates that an asynchronous set or clear inactive edge cannot occur within *check_value* before the closing clock edge. This is essentially a setup requirement on an asynchronous pin, but only the inactive

transition is considered.

The **-removal** option indicates that an asynchronous set or clear inactive edge cannot occur until *check_value* time after the closing clock edge. This is essentially a hold requirement on an asynchronous pin, but only the inactive transition is considered.

The **-nochange_high** option provides a timing check that indicates that the data must not rise within *check_value* time before the clock becomes active and must not fall until *check_value* time after the clock becomes inactive.

The **-nochange_low** option provides a timing check that indicates that the data must not fall within *check_value* time before the clock becomes active and must not rise until *check_value* time after the clock becomes inactive.

-rise | -fall

Specifies whether the check is for data rise or fall transition. If you do not specify either **-rise** or **-fall**, both values are set.

The **-rise** option specifies a rise data transition that corresponds to the check before the activating clock edge. A rise data transition corresponds to the check after the deactivating clock edge. A rise clock transition indicates that the clock is active-high.

The **-fall** option specifies a fall data transition that corresponds to the check after the deactivating clock edge. A fall data transition corresponds to the check before the activating clock edge. A fall clock transition indicates that the clock is active-low.

-clock *clock_check*

Specifies whether the check is for clock rising or falling. Valid values for *clock_check* **rise** and **fall**. By default, checks for both clock rise and fall are set.

-worst

Specifies that the check is to overwrite the previously-annotated check only if the *check_value* specified is worse than the check value previously annotated. By default, *check_value* overwrites any previously-annotated value.

DESCRIPTION

Annotates a timing check between two or more pins on a cell or a net in the *current design*. This might be appropriate after place and route, for technologies where the timing check value varies for different instances and the library timing check values do not provide sufficient accuracy.

If the design is not already linked, **set_annotated_check** links it automatically.

The command can be used for pins at lower levels of the design hierarchy. Pins are specified as "INSTANCE1/INSTANCE2/PIN_NAME."

To list annotated timing check values, use the **report_annotated_check** command. To remove annotated timing check values from a design, use the **remove_annotated_check** or **reset_design** command. To see the affect of **set_annotated_check** for a specific instance, use the **report_timing** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example annotates a setup time of 2.1 units between clock pin *CP* of cell instance *u1/ff12* and data pin *D* of the same cell instance.

```
prompt> set_annotated_check -setup 2.1 -from u1/ff12/CP \
-to u1/ff12/D
```

The following example annotates a nochange check between data low and clock low. The nochange margin before the clock is 1.3 and the nochange margin after the clock is 2.4.

```
prompt> set_annotated_check -nochange_low 1.3 -clock fall \
-fall -from u1/CP -to u1/EN
prompt> set_annotated_check -nochange_low 2.4 -clock fall \
-rise -from u1/CP -to u1/EN
```

SEE ALSO

```
current_design(2)
link(2)

report_annotated_check(2)
report_timing(2)
reset_design(2)
```

set_annotated_delay

Sets the net or cell delay value between two pins.

SYNTAX

```
int set_annotated_delay
    -net | -cell
    [-load_delay load_delay_type]
    [-rise | -fall] [-min] [-max] delay_value
    -from from_pins -to to_pins [-worst]
```

Data Types

<i>delay_value</i>	float
<i>from_pins</i>	list
<i>to_pins</i>	list

ARGUMENTS

```
-net | -cell
    Specifies whether the delay annotated is a net or cell delay. This is a required argument.

-load_delay load_delay_type
    Specifies whether to include load delay as part of annotated net delays or as part of annotated cell delays. load_delay_type must be the value of net or cell. Load delay is the portion of cell delay arising from the capacitive load of the net the cell is driving. Set location_name to either net or cell. All timing arcs of the same net must be annotated with the same location_name; and all timing arcs of the same cell must be annotated with the same location_name.

-rise | -fall
    Specifies whether the delay is for data rise or fall transition. If you don't specify -rise or -fall, both values are set.

-min -max
    Specifies whether the delay is to be used for minimum delay analysis or maximum delay analysis. By default, the delay is used for maximum and minimum delay analysis. If a delay value is annotated for only minimum or maximum delay analysis, that value is used for both maximum and minimum delays. It is possible to annotate different delay values for minimum and maximum analysis, but it is not possible to annotate only for minimum or annotate only for maximum.

delay_value
    Specifies the delay value between pins on the same cell or net. The delay_value must be expressed in units consistent with the technology library used during optimization. For example, if the technology library specifies delay values in nanoseconds, delay_value must be expressed in nanoseconds.
```

```

-from from_pins
    Specifies a list of leaf cell pins or top-level ports that are the startpoints
    of the timing arcs for which delays are to be annotated.

-to to_pins
    Specifies a list of leaf cell pins or top-level ports that are the endpoints
    of the timing arcs for which delays are to be annotated.

-worst
    Indicates that the delay is to overwrite the previously annotated delay only
    if the delay_value specified is worse than the delay value previously
    annotated. By default, delay_value overwrites any previously annotated value.

```

DESCRIPTION

Annotates the cell delay between two or more pins on a cell in the current design or the net delay between two or more pins on the same net. With the **-net** option, pins in *from_pins* must be cell output or inout pins, and pins in *to_pins* must be cell input or inout pins. With the **-cell** option, both **-from** and **-to** options are required; pins in *from_pins* must be cell input or inout pins, and pins in *to_pins* must be cell output or inout pins. To verify the accuracy of the back-annotation done by **set_annotated_delay**, run **update_timing**.

If the current design is hierarchical, you must link it using **link -all** before using **set_annotated_delay**.

Load delay, also known as extra source gate delay, is the portion of cell delay caused by the capacitive load of the net being driven. Some delay calculators consider load delay part of the net delay and others consider it part of the cell delay. If your annotated delay value (for either cell or net) assumes that load delay is part of the cell delay, use **-load_delay cell**. If your delay value assumes that load delay is included in the net delay, use **-load_delay net**. By default, load delays are assumed to be in cell delays; and so they appear in **report_timing** path listings.

The specified delay value overrides the internally-estimated cell and net delay value. If the specified pins are not in the same cell or on the same net, then when the timing is updated an error message is generated and *delay_value* is discarded for those pins.

You can use **set_annotated_delay** for pins at lower levels of the design hierarchy. Pins are specified as "INSTANCE1/INSTANCE2/PIN_NAME."

To list annotated delay values, use **report_annotated_delay**. To remove the annotated cell or net delay values from a design, use **remove_annotated_delay** or **reset_design**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example annotates a cell delay of 20 units between input pin "A" of cell instance "U1/U2/U3" and output pin "Z" of the same cell instance. The delay value of 20 includes the load delay.

```
prompt> set_annotated_delay -cell -load_delay cell 20 -from U1/U2/U3/A -to U1/U2/U3/Z
```

The following example annotates a rise net delay of 1.4 units between output pin "U1/Z" and input pin "U2/A". The delay value for this net does not include load delay.

```
prompt> set_annotated_delay -net -rise -load_delay cell 1.4 -from U1/Z -to U2/A
```

The following example annotates a rise net delay of 12.3 units for minimum delay analysis between the same output pins. In this case the net delay value does include load delay.

```
prompt> set_annotated_delay -net -rise -min -load_delay net 12.3 -from U1/Z -to U2/A
```

set_annotated_transition

Sets the transition time at a given pin.

SYNTAX

```
int set_annotated_transition
[-rise | -fall] [-min] [-max] transition
port_pin_list
```

Data Types

<i>transition</i>	float
<i>port_pin_list</i>	list

ARGUMENTS

-rise | -fall

Specifies whether the transition time is for data rise or data fall transition. If you do not specify **-rise** or **-fall**, both values are set.

-min -max

Specifies whether the transition is to be used for minimum delay analysis or maximum delay analysis. By default, the transition value is used for maximum and minimum delay analysis. If a transition value is annotated for only minimum or maximum delay analysis, that value is used for both maximum and minimum delays. It is possible to annotate different transition values for minimum and maximum analysis, but it is not possible to annotate only for minimum or annotate only for maximum.

transition

Specifies the transition value at the pins supplied with the *port_pin_list* argument. The transition value must be expressed in units consistent with the technology library used during optimization. For example, if the technology library specifies transition values in nanoseconds, the transition values must be expressed in nanoseconds.

port_pin_list

Specifies a list of leaf cell pins or top-level ports that are the endpoints of the timing arcs for which delays are to be annotated.

DESCRIPTION

To list annotated transition values, use **report_annotated_transition**. To remove the annotated transition values from a design, use **remove_annotated_transition** or **reset_design**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example annotates a transition time of 20 units at input pin "A" of cell instance "U1/U2/U3".

```
prompt> set_annotated_transition 20 U1/U2/U3/A
```

The following example annotates a rise transition of 1.4 units at the input pin "U5/A".

```
prompt> set_annotated_transition -rise 1.4 U5/A
```

The following example annotates a rise transition of 12.3 units for minimum delay analysis at U5/A.

```
prompt> set_annotated_transition -rise -min 12.3 U5/A
```

set_attribute

Sets an attribute to a specified value on the specified list of objects.

SYNTAX

```
collection set_attribute
[-class class_name]
object_list
attribute_name
attribute_value
[-quiet]
```

Data Types

<i>class_name</i>	string
<i>object_list</i>	list
<i>attribute_name</i>	string
<i>attribute_value</i>	string

ARGUMENTS

-class *class_name*
Specifies the class name for the object specified in *object_list*, if the element of *object_list* is a name. Valid classes are design, port, cell, net, etc.

object_list
A list of objects on which the attribute is to be set. Each element in the list is either a collection or a pattern that is combined with the *class_name* to find the objects.

attribute_name
Specifies the name of the attribute to be set.

attribute_value
Specifies the value of the attribute. The data type must be the same as that of the attribute.

-quiet
Turns off the warning message that would otherwise be issued if the attribute or objects are not found.

DESCRIPTION

This command sets the value of an attribute on an object. For a complete list of attributes, see the **attributes** man page.

This command creates a collection of objects that have the specified attribute value set. A returned empty string indicates that no object has been set.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example defines an attribute named `X` for cells, then sets the value on all cells in this level of the hierarchy:

```
prompt> define_user_attribute -type int -class cell X
cell
prompt> set_attribute [get_cells *] X 30
{"U1"}
```

SEE ALSO

`collections(2)`
`define_user_attribute(2)`
`get_attribute(2)`
`list_attributes(2)`
`remove_attribute(2)`

set_auto_disable_drc_nets

Sets the **auto_disable_drc_net** attribute on the current design, causing the specified networks to be have DRC disabled. This command was previously called **set_auto_ideal_nets**.

SYNTAX

```
int set_auto_disable_drc_nets
[-default]
[-none]
[-all]
[-clock true | false]
[-constant true | false]
[-scan true | false]
```

ARGUMENTS

-default
Disables design rule checking (DRC) on nets in clock trees and constant nets in the *current design*; equivalent to **-clock true** and **-constant true**. This is also the default behavior if no option is selected or if the command is not executed. You cannot use **-default** with any other option.

-none
Enables DRC for all networks in the *current design*, including nets in clock trees. You cannot use **-none** with any other option.

-all
Disables DRC on all applicable nets in the *current design*. It is equivalent to setting **-clock true**, **-constant true**, and **-scan true**.

-clock true | false
Disables or enables DRC on clock networks in the *current design*. When **true** (the default), it automatically disables DRC on only clock networks: When **false**, it enables DRC on them. By default, Design Compiler treats clock networks as ideal nets even if this command is not executed. To disable this default behavior and prevent clock networks from being treated as ideal nets, set this option to **false**.

-constant true | false
Disables or enables DRC on constant nets in the *current design*. When **true** (the default), it automatically disables DRC on constant nets: When **false**, it enables DRC on them.

-scan true | false
Disables or enables DRC on scan nets in the *current design*. When **true**, it automatically disables DRC on scan nets: When **false** (the default), it enables DRC on them. This option does not prevent Design Compiler from automatically disabling DRC on clock networks and constant nets, unless **-clock false** and **-constant false** is also used.

DESCRIPTION

Disables design rule checking for specified networks in the *current design*. If the command is executed without options, or if the command is not executed at all, by default, Design Compiler disables DRC for all clock nets and constant nets. The command options are additive each time a new **set_auto_disable_drc_nets** command is executed.

To prevent clock nets from having DRC disabled, use the **-clock false** or **-none** options.

To prevent constant nets from having DRC disabled, use the **-constant false** or **-none** options.

DRC disabled nets are a network of nets that are free from the `max_capacitance`, `max_fanout`, and `max_transition` design rule constraints. They are useful for reducing DRC violations caused by clock trees, because these networks usually have high `max_capacitance` and `max_fanout` violations.

You can add the **dont_touch** attribute to the DRC disabled nets by using the **set_dont_touch_network** or the **set_dont_touch** command.

Note that auto_disable_drc nets are different from ideal_nets and ideal_networks, since these also use ideal timing and set dont_touch on the nets (and cells, in the case of ideal_networks).

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example disables DRC on clock trees and constant nets in the *current design*.

```
prompt> set_auto_disable_drc_nets -clock true -constant true
```

The following example disables DRC on only the constant nets in the *current design*.

```
prompt> set_auto_disable_drc_nets -constant true
```

The following example re-enables DRC for all relevant nets, including those on clock networks, from the *current design*.

```
prompt> set_auto_disable_drc_nets -none
```

set_ideal_network(2)
```

set_buffer_opt_strategy

Invokes new buffering strategy.

SYNTAX

```
int set_buffer_opt_strategy
[-effort string]
```

ARGUMENTS

-effort none | low | medium | high

Specifies the effort level for the new buffering strategy. The default effort level is **medium**. The different effort levels dictate the amount of time spent in the new buffering strategy. Typically, a higher effort level will result in better reduction in buffer and inverter counts. The **none** effort level can be used to turn off the new buffering strategy.

DESCRIPTION

The fbset_buffer_opt_strategy command invokes a new buffering strategy, that reduces buffer and inverter counts, without significantly affecting the quality of results (QoR).

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies high-effort buffering strategy.

```
prompt> set_buffer_opt_strategy -effort high
```

The following example turns off the new buffering strategy. prompt>
set_buffer_opt_strategy -effort none

set_case_analysis

Specifies that a port or pin is at a constant logic value 1 or 0, or is considered with a rising or falling transition..

SYNTAX

```
string set_case_analysis
value
port_or_pin_list
```

Data Types

port_or_pin_list list

ARGUMENTS

value 0 / 1 / zero / one / rise / fall / rising / falling

Specifies the constant logic value or the transition to assign to the given pin or port. The valid constant values are **0**, **1**, **zero**, or **one**. Transition values can be **rising**, **falling**, **rise**, and **fall**.

port_or_pin_list

Lists ports or pins to which the case analysis is assigned. The command performs no backward constant propagation.

DESCRIPTION

Specifies that a port or pin is at a constant logic value 1 or 0.

Case analysis is a way to specify a given mode of the design without altering the netlist structure. For the current timing analysis session, you can specify either that some signals are at a constant value (1 or 0) or that only one type of transition (rising or falling) is to be examined. When you specify case analysis to a constant value, the constant value is propagated through the network as long as a controlling value for the traversed logic is at the constant value.

For example, if you specify that one of the inputs of a NAND gate is a constant value 0, it is propagated to the NAND output, which is now considered at a logic constant 1. This propagated constant value, itself, is propagated to all cells driven by this signal.

In the event of case analysis on transition, the given pin or port is only considered for timing analysis with the specified transition. The other transition is disabled.

All analysis commands use case analysis information, including the false-path detection algorithm used by the **report_timing** command with the **-true** option and the **report_timing** command with the **-justify** option.

You can use case analysis (in addition to the mode commands) to fully specify the mode of a design. For example, you can use the **set_mode** command to specify a design

that instantiates models with a TESTMODE that is disabled during the timing analysis session. In addition, if a TESTMODE signal exists on the design, it is specified to a constant logic value, so that all test logic that the TESTMODE signal controls is disabled.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example specifies that a port named *IN1* is at a constant logic value 0.

```
prompt> set_case_analysis 0 IN1
```

The following example specifies how to disable the TESTMODE of a design for which instances are models having a TESTMODE mode. The design also has a *TEST_PORT* port set to a constant logic value 0.

```
prompt> remove_mode TESTMODE U1/U2
prompt> set_case_analysis 0 TEST_PORT
```

The following example specifies that the pins U1/U2/A is only considered for a rising transition. The falling transition on these pins are disabled.

```
prompt> set_case_analysis rising U1/U2/A
```

SEE ALSO

```
remove_case_analysis(2)
report_case_analysis(2)
set_mode(2)
```

set_cbt_options

Sets options used by the **create_buffer_tree** command.

SYNTAX

```
int set_cbt_options
[-threshold threshold_value]
[-references list_of_references]
[-default]
[-cluster_mode_cluster_size int_0]
```

Data Types

threshold_value int

ARGUMENTS

-threshold *threshold_value*

Specifies a fanout threshold used by the **create_buffer_tree** command to search for high fanout nets. The default value is 100.

-references *list_of_references*

Specifies a list of library cells (buffers and inverters) the **create_buffer_tree** command can use. If not specified, all library buffers and inverters can be used.

-default

Resets all the options to their default values. This option cannot be combined with any other option.

DESCRIPTION

The **set_cbt_options** command sets options used by the **create_buffer_tree** command. These options take effect only when **set_ahfs_options -optimize_buffer_trees false** is specified.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
set_cbt_options -threshold 1000 -references {BUFFLV3 INVLV3}
```

SEE ALSO

create_buffer_tree(2)
report_cbt_options(2)

set_cell_degradation

Sets the **cell_degradation** attribute to a specified value on specified ports or designs.

SYNTAX

```
int set_cell_degradation  
cell_degradation_value  
object_list
```

Data Types

<i>cell_degradation_value</i>	float
<i>object_list</i>	list

ARGUMENTS

cell_degradation_value

Specifies a capacitance value for setting the **cell_degradation** attribute. You must express *cell_degradation_value* in capacitance units consistent with that used by the technology library during optimization. For example, if the library specifies capacitance values in picofarads, you must express *cell_degradation_value* in picofarads.

object_list

Specifies a list of names of input ports for setting the **cell_degradation** attribute.

DESCRIPTION

Sets the **cell_degradation** attribute to *cell_degradation_value* on the specified ports or designs. During optimization, the tool attempts to ensure that the capacitance value for a net is less than the *cell_degradation_value* if the value of the variable **compile_fix_cell_degradation** is true.

If cell degradation tables are already specified in a technology library (implicit constraints), **compile** automatically tries to meet them if the value of the variable **compile_fix_cell_degradation** is true. The cell degradation tables give the maximum capacitance that can be driven by a cell as a function of the transition times at the inputs of the cell.

By default, a port has no cell degradation constraint.

The **cell_degradation** attribute and the **max_capacitance**, **max_fanout**, and **max_transition** attributes are design rule constraints; the **max_delay** and **max_area** attributes are optimization constraints. Design rule constraints reflect those technology-specific restrictions that MUST be met for a design to function correctly. Optimization constraints reflect desirable, but not crucial goals and restrictions for the operation of a design. The tool attempts to meet all constraints placed on a design, but gives priority to design rule constraints in the optimization process. Therefore, optimization gives preference to **cell_degradation**.

and other design rule constraints, even if they adversely affect optimization constraints on a design.

To get information about optimization and design rule constraints, use **report_constraint**. To remove the **cell_degradation** attribute from a port, use **remove_attribute**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets a maximum capacitance value of 2.0 units on the port named late_riser:

```
prompt> set_cell_degradation 2.0 late_riser
```

SEE ALSO

```
all_inputs(2)
all_outputs(2)
characterize(2)
remove_attribute(2)
report_constraint(2)
set_max_capacitance(2)
```

set_cell_internal_power

Sets or removes the **power_value** attribute on the specified pins. The value represents the power consumption for a single toggle of each pin.

SYNTAX

```
int set_cell_internal_power
[-delete_all]
pin_list
[power_value [unit]]
```

Data Types

<i>pin_list</i>	object list
<i>power_value</i>	float
<i>unit</i>	string

ARGUMENTS

-delete_all
Deletes all of the internal power annotations from all of the pins in the design.
This option cannot be used with *pin_list*, *power_value*, or *unit*.

pin_list
Specifies a list of pins on which to either set the **power_value** attribute, or remove previously-annotated **power_value** attributes.
This option cannot be used with the **-delete_all** option.

power_value
Specifies the value with which the **power_value** attribute is to be set on the specified pins. If *power_value* is not specified, any existing **power_value** attributes are removed from the specified pins.
This option cannot be used with the **-delete_all** option.

unit
Specifies the unit of the power value. Allowed values for *unit* are as follows:
GW MW KW W mW
uW nW pW fW aW
If *unit* is not specified, the tool uses the library power unit. If the library does not have any units, the tool displays an error message.
This option cannot be used with the **-delete_all** option.

DESCRIPTION

This command sets or removes the **power_value** attribute on specified pins. The *power_value* is the value with which to set the **power_value** attribute, and represents the power consumption for a single toggle of the pin. If a cell has at least one such annotated pin, its internal power is calculated as the sum of the pin power values, where each pin power value is calculated by multiplying the annotated power value on that pin by the pin toggle rate.

If this command is issued without the *power_value* argument, the tool removes any existing **power_value** attributes from the specified pins. If the *power_value* argument is specified without *unit*, the tool uses the power unit of the library. If the library does not have any units, the tool generates an error message.

Use this command to override a cell's library power characterization in situations where that characterization does not apply. A common use is when you manually replace an entire cloud of logic with a single cell and you want the single cell's power consumption to represent that of the cloud of logic. For example, if you replace a clock tree by a single buffer cell, you can set the **power_value** attribute on the output pin of the buffer cell with the value of the power consumption for one clock toggle of the entire clock tree. Although the buffer cell might have been power-characterized in the library, its power consumption is now calculated using the value of the **power_value** attribute set by the **set_cell_internal_power** command.

Do not use this command as a routine part of the power characterization flow. It is considered best practice to use a cell's library power characterization unless there is a reason to override it, as described above.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows how an instance-specific cell is power-characterized using the **set_cell_internal_power** command:

```
prompt> set_cell_internal_power [get_pins U123/A] 1.234 uW
prompt> set_cell_internal_power [get_pins U123/B] 1.567 uW
prompt> set_cell_internal_power [get_pins U123/*] -1.000 nW
prompt> set_cell_internal_power -delete_all
```

SEE ALSO

`report_power(2)`

set_cell_location

Specifies the physical location for leaf cells.

SYNTAX

```
int set_cell_location
object_list
-coordinates {X Y}
[-ignore_fixed]
```

ARGUMENTS

object_list
Specifies the list of cells object, each of which is a leaf cell. Typically, this command uses a single cell as the argument.

-coordinates {X Y}
Specifies the lower left coordinates of the specified cell(s). The numbers are in microns relative to the chip origin.

DESCRIPTION

The **set_cell_location** command specifies the physical location for leaf cells. It overwrites the existing information, but not the CLUSTER move_bounds.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the location of the cell named INST_1 to the coordinates {100 100}.

```
prompt> set_cell_location -coordinates {100 100} INST_1
```

SEE ALSO

`create_placement(2)`
`set_dont_touch_placement(2)`
`write_physical_constraints(2)`

set_cell_row_type

Binds the logical hierarchical module to the specified row type attribute.

SYNTAX

```
int set_cell_row_type
    -type row_type
    cell_list
```

Data Types

<i>row_type</i>	int
<i>cell_list</i>	list

ARGUMENTS

-type *row_type*
Specifies the row type identifier that is set on hierarchical cells.

cell_list
Specifies one or more submodules in the design.

DESCRIPTION

The **set_cell_row_type** command sets a row type for a specified list of cells. The cells must be logical hierarchies and should not already have a row type attribute set.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to set the row type identifier to 1 for the cells "I_ALU" and "I_CONTROL".

```
prompt> set_cell_row_type -type 1 I_ALU I_CONTROL
```

SEE ALSO

`set_row_type(2)`

set_cell_type

Changes the **cell_type** attribute on any library reference cell so you can set or unset any cell as a macro cell.

SYNTAX

```
status set_cell_type
      -type BLOCK | COVER | RING | PAD | CORE
      list_of_library_reference_cells
```

Data Types

list_of_library_reference_cells string

ARGUMENTS

-type BLOCK | COVER | RING | PAD | CORE
Specifies the **cell_type** attribute.

list_of_library_reference_cells
Specifies the list of library reference cells on which to change the **cell_type** attribute.

DESCRIPTION

This command changes the **cell_type** attribute on the specified library reference cells. You specify the library reference cells in the input list, and the command changes the **cell_type** attribute on each one. Setting the library reference **cell_type** attribute to one of the valid types gives you the control to set or unset any cell as a macro cell. Valid cell types are BLOCK, COVER, RING, PAD, and CORE.

After you change any library reference cell to one of the valid cell types, all netlist cells instantiated from these library cells are treated like the specified cell type.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the cell type of the libram512 library reference cell to **block**.

```
prompt> set_cell_type -type BLOCK libram512
```

Note that every library cell already has a *cell_type* attribute and these attributes are overwritten in the current session after running this

command.

You can also specify the cell_type as **CORE** or **PAD** to remove the macro cell attributes.

A **cell_type** attribute set by using the **set_cell_type** command is not a permanent attribute set on library cells.

These attributes last only for the current session, unless you invoke a **write_lib** command in the current session.

After invoking a **write_lib** command, these attributes are written to a new library and then are persistent.

SEE ALSO

`all_macro_cells(2)`
`write_lib(2)`

set_cell_vt_type

Sets the threshold voltage type of a library cell or of all cells of a library. The threshold voltage type is used for mixed threshold voltage filler cell insertion.

SYNTAX

```
status set_cell_vt_type
      -library library_name | -lib_cell cell_name
      -vt_type
```

Data Types

<i>library_name</i>	string
<i>cell_name</i>	string

ARGUMENTS

Use this option to set the specified library cell to be the indicated vt type.

-library *library_name* | -lib_cell *cell_name*

Use -library to specify a library name or -lib_cell to specify a cell name.

-vt_type *vt_type_name*

Specifies the name of the vt type to be set to the library cell or the cells of a library

DESCRIPTION

Use this command to set vt type string of a library cell or cells of a library.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets vt type VtType1 to library cell MasterA

```
prompt> set_cell_vt_type -lib_cell "MasterA" -vt_type "VtType1"
```

SEE ALSO

```
insert_stdcell_filler(2)
set_vt_filler_rule(2)
remove_cell_vt_type(2)
report_cell_vt_type(2)
```

set_check_library_options

Sets specific options for the **check_library** command for logic library versus logic library checking, logic library versus physical library checking, and for checks between physical libraries.

SYNTAX

```
status set_check_library_options
[-cell_area]
[-cell_footprint]
[-bus_delimiter]
[-tech_consistency]
[-view_comparison]
[-same_name_cell]
[-signal_em]
[-antenna]
[-rectilinear_cell]
[-physical_only_cell]
[-phys_property {property_list}]
[-routeability]
[-tech]
[-drc]
[-scaling {scaling_types}]
[-mcmm]
[-upf]
[-compare {construct | attribute | value}]
[-tolerance {type relative_tolerance absolute_tolerance}]
[-validate {validation_types}]
[-va_analysis {std_error=val_err slope=val_sl trend=['/' | '' | '^' | 'V']}]
[-nosplit]
[-physical]
[-logic_vs_physical]
[-logic]
[-reset]
[-all]
```

Data Types

<i>property_list</i>	list
<i>scaling_types</i>	list
<i>type</i>	string
<i>relative_tolerance</i>	float
<i>absolute_tolerance</i>	float
<i>validation_types</i>	list

ARGUMENTS

-cell_area

Compares the area of the cells in the logic library (set by the area attribute) against the area set by the cell PRBoundary in the physical library. In the FRAM view, the ratios of the PRBoundary for standard cells in a rectangle, or the ratios of the CellBoundary for macros in a polygon,

are compared against the cell area in the .db file. If the ratio is the same for all the cells in the library, the cell areas are considered to be consistent. If the ratio for a cell deviates from the normal or average ratio for this library by a margin of 5 percent, it is counted as an inconsistent area.

There is no area check for pad cells. A pad cell is a special cell at the chip boundary in a logic cell. Pad cells are not checked because they are not used as internal gates and always have an area of 0.

The default logic versus physical checks are also enabled with this option.

-cell_footprint

Checks that the cell PR boundary in the physical library is consistent among a class of cells when the same **cell_footprint** attribute is specified in the logic library. This option reports cell names and their PR boundaries grouped by the **cell_footprint** string.

The default logic versus physical checks are also enabled with this option.

-bus_delimiter

Reports bus delimiters in logic and physical libraries. If there is no bus delimiter in the library, the field is blank in the report.

The default logic versus physical checks are also enabled with this option.

-tech_consistency

Checks for technology data consistency between the main library or design library and each associated reference library. The option checks the physical libraries for missing layer data and mismatched technology data.

-view_comparison

Checks for the existence of CEL and FRAM views in the library and for mismatched time stamps between these views. In the report table for missing views, the CEL and FRAM columns list the cell name and version number. An X marks the view that is missing.

In the report table for mismatched views, the CEL version and FRAM version columns list the version numbers, and the CEL and FRAM modified time column lists the time when the view was last modified. If a cell has an earlier FRAM view than its CEL view, it is marked as mismatched.

The time that is checked is the internal view creation or modification time in the Milkyway database, not the UNIX time. No mismatch check is performed on the cell content. If you read FRAM views from the LEF and then stream in CEL views, the views are shown as mismatched. You can ignore this report in this case.

-same_name_cell

Checks for cells with identical names among the specified main or design library and all physical reference libraries linked to the specified library. If there are cells with the same name in multiple reference libraries, the tool uses the first cell in the reference control file and ignores the remaining cells. This option does not check naming among the logic libraries.

-signal_em

Checks for the signal electromigration rule (current model and model type) for each routing layer.

-antenna

Checks for missing antenna properties for cells and antenna rules in the

layers in the specified main library.

In the missing antenna property table, it lists the cell names and pin names that are missing the antenna property and the missing property type. If an input pin is missing the gate size, it is counted as missing the property. If an output pin is missing diode protection, it is counted as missing the property. If a macro is missing the hierarchical antenna property, it is counted as missing the property. You should specify hierarchical antenna properties for macros.

This option reports the mode, diode mode, default metal ratio, default cut ratio and maximum ratio for each antenna rule.

-rectilinear_cell

Checks and reports the cell names, types, and coordinates of cells with rectilinear boundaries.

-physical_only_cell

Checks and reports the cell names, types, and properties of physical-only cells.

Physical-only cells are filler cells with and without metal, corner pad cells, tap cells, chip cells, I/O pad cells, cover cells and cells that only have power and ground pins.

-phys_property {property_list}

Specifies a list of physical properties to check. You can specify one or more of the following values:

- **place** reports the following placement properties for each standard cell:
 - * PR boundary as represented by its lower-left and upper-right coordinates.
 - * Cell height relative to the unit tile height, such as 1xH for single height.
 - * Coordinate, the bottom-left location for a single-height cell or left locations at each unit height for a multiple-height cell.
 - * Tile pattern representing possible cell orientations that can have combinations of R0, R90, R160, R0_MX, R0_MY, 90_MX, and R90_MY.
 - * Remarks noting that the PR boundary mismatches the tile pattern. If mismatched, use the **cmSetMultiHeightProperty** command to set the tile patterns for multiple-height cells.
 - * For macros, the option reports the cell boundary and height.

When you specify the **place** argument, it also lists the main library and its reference library names with paths, if any, and the unit tiles names and sizes. The unit tile size is reported in the format of width x height. If no tile size is reported, the library has no unit tile and the unit tile in the main library is used in the design.

- **route** checks and reports the routing properties for each routing layer including the preferred direction, track direction, offset, pitch, and remarks. The remarks column shows OK if the offset is 0 or half pitch; otherwise, it marks pitch=0 or offset!=0.5*pitch.

- **cell** reports the cell and pin properties for each cell including pin name, direction, and type. It also reports the number of cells with multiple power and ground pins.

- **metal_density** checks the macro metal density data for the cells specified by the **check_library** command with the **-cells** option. The option checks if a cell has at least one of the following errors:

- * The metal density data in the CEL view and FRAM view are inconsistent
- * The metal density windows do not cover the entire area on a layer

The option lists all of the cells with metal density errors in a table with columns showing the cell name, data inconsistency between the CEL view and FRAM view, and on which layer the density windows do not cover the entire area.

-routeability

Checks the physical pin on-track accessibility and quality of defined wire tracks. The option reports the total number of pins without optimal on-track routability and lists the pin names, directions, layers, and tracks for each cell with this issue.

In the track column, an H denotes that the pin is not accessible on a horizontal track, a V denotes the pin is not accessible on a vertical track, and H&V denotes that the pin is not accessible on both horizontal and vertical tracks.

If a pin is reported as not accessible on-track, the pin might be routed by an off-track wire during detail routing. If too many pins do not have any on-track routability, adjust the offset values of the wire track (0 or half pitch is preferred) and rerun the **create_lib_track** command to reduce the number of pins without optimal accessibility.

If routability checking is not successful, the cause might be no unit tile or incorrect technology data, such as an illegal fat wire threshold for some layers, illegal vias or cut layers, an illegal layer number, and undefined rules.

It is possible that a track intersection is inside a via region but there is not optimal routability. This can happen because the tool considers the worst case when checking the routability, for example if a via is already dropped in a neighboring pin's via region, making the via spot that is from the via region of the pin being checked smaller.

-tech

Checks for the technology data in the specified library. This check is different from the checking done by **-tech_consistency** in that this option checks the technology data in the single library. The messages of the checking are similar to those during library creation or technology data replacement. This option requires that the directory where the library resides has write permission. If the library is not writable, it is copied to the local library first, and then the local library is checked.

-drc

Specifies DRC checks for the routing (FRAM) view of cells in the specified library. It checks the following design rules:

```
wire minWidth  
minEdgeLength  
minEnclosedArea  
minSpacing  
cutWidth  
cutSpacing  
minEnclosure  
sameNetMinSpacing  
maxStackLevel  
fatTblSpacing  
metal-via spacing (minSpacing in DesignRule)
```

It lists the cells with DRC violations in a table with columns showing the cell name, type, and error cell. Check the error cells for details of DRC violations. This option requires that the directory where the library resides has write permission.

-scaling {scaling_types}

Specifies a list of logic library consistency checks for various types of scaling.

You can specify one or more of the following values:

- **timing** specifies logic library consistency checking for CCS timing scaling.
- **noise** specifies logic library consistency checking for CCS noise scaling.
- **power** specifies logic library consistency checking for CCS or NLDM power scaling (driver and receiver models, load indices, base curve_x, waveform, noise, and power models.)

-mcmm

Specifies logic library consistency checking for multicorner-multimode (power_down_function and power data).

-upf

Specifies logic library consistency checking for multivoltage and UPF (power special cells, pg_pin, voltage_names, power_down_function, and power data).

-compare {construct | attribute | value}

Compares all groups, subgroups, and attributes between the logic libraries.

You can specify one of the following values:

- **-compare {construct}** checks if constructs or attributes are missing.

• **-compare {attribute}** checks if constructs and attributes are missing and if attribute values are inconsistent.
It checks all groups and subgroups and all attribute values except characterization values.
It is a superset of **-compare {construct}**.

- **-compare {value}** compares values of each group and attributes between the libraries.

It is a superset of the **-compare {attribute}**.

In comparing characterization values, if the source is not from .lib files, the values are not reported, such as values in vectors and capacitances.

The comparison of values are controlled by tolerances specified by **-tolerance** or by default values if **-tolerance** is unspecified.

For minimum and maximum library checking and scaling group library checking, you should specify **-compare {attribute}** to check all library contents except characterizations.

When you specify this option, the following default checks are also performed: missing cells, missing and mismatched pins, and timing arcs.

-tolerance {type relative_tolerance absolute_tolerance}

Specifies a relative tolerance and an absolute tolerance for characterization value comparison, such as delay values.

The format is

-tolerance {type rel_tol abs_tol}

where the valid values for the type argument are delay, slew, constraint, slew_index, load_index, time, power, current, and capacitance. If the type is not specified, the values are for output load capacitance. To specify an absolute tolerance, do not include the unit. The unit in the first library is used. For example, to specify tolerances for delay and slew, use:

-tolerance {delay 0.1 0.2 slew 0.3 0.4}

If you do not specify tolerances for a type, default values are used. The default values are set as follows in compliance with PrimeTime and the Library Quality Assurance System:

Relative tolerance for load index	:	0.01
Absolute tolerance for load index	:	0.001pF
Relative tolerance for time	:	0.04
Absolute tolerance for time	:	0.015ns
Relative tolerance for power	:	0.04
Absolute tolerance for power	:	5pW

-validate {validation_types}

Specifies logic library consistency checking for library characterization between different models. You can specify one or more of the following values: **timing** and **power**.

-va_analysis {std_error=val_err slope=val_slope trend=['/' | '' | '^' | 'V']}

Specifies variation-aware (VA) analysis criteria. The std_error and slope are for linear regression models and trend_symbol includes five symbols:

// = monotonously increasing
<HardSpace= monotonously decreasing
^ = non-monotonously up
V = non-monotonously down
- = flat

To specify monotonous decreasing (\), use {trend = ''}. In the expressions of std_error and slope, the sign can also be <. or =. For trend, inequality

can be specified by !=. The VA analysis reports the results that meet any of the specified criteria (expressions).

-nosplit

Prevents prevents line-splitting and facilitates writing software to extract information from the report output. Most of the information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-physical

Includes the following physical checking options:

- tech_consistency
- view_comparison
- same_name_cell
- signal_em
- antenna
- rectilinear_cell
- physical_only_cell
- phys_property {place route}
- routeability
- tech
- drc

-logic_vs_physical

Checks all logic versus physical library checking including the default checks for missing cells and missing or mismatched pins in the logic or physical library and the following checks:

- cell_area
- cell_footprint
- bus_delimiter

-logic

Includes all of the following logic library checking options:

- scaling
- mcm
- upf

-reset

Resets the options to the default, meaning that missing cells and missing or mismatched pins are checked between logic and physical libraries. All other options are ignored if used with the **-reset** option.

-all

Checks all of the following for the library:

- tech_consistency
- view_comparison
- same_name_cell
- signal_em
- antenna
- rectilinear_cell
- physical_only_cell

```
-phys_property {place route cell metal_density}
-routeability
-tech
-drc
-logic_vs_physical
-logic
```

DESCRIPTION

The **set_check_library_options** command sets specific options for the **check_library** command for logic library versus logic library checking, logic library versus physical library checking, and for checks between physical libraries.

Run the **set_check_library_options** command before running **check_library**. If you do not specify options with **set_check_library_options**, by default the command checks missing cells and pins and mismatched pins, including pg_pins versus power and ground pins.

A status indicating success or failure is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, the **-cell_footprint** and **-bus_delimiter** options are set, the lib1.db and lib2.db logic libraries are checked against the phys_lib physical libraries for missing cells and pins, mismatched pins, the cell footprints are compared, and the bus delimiters are checked:

```
prompt> set_check_library_options -cell_footprint \
           -bus_delimiter
1
prompt> check_library -mw_library_name {phys_lib} \
           -logic_library_name {lib1.db lib2.db}
1

#BEGIN_XCHECK_LIBRARY

`report_check_library_options(2)`

set_checkpoint_strategy

Set the checkpoint strategy for preroute optimization commands

SYNTAX

```
int set_checkpoint_strategy
[-enable | -disable]
[-overwrite]
[-prefix prefix]
```

ARGUMENTS

[-enable | -disable]

These exclusive options will either enable checkpoint creation or disable checkpoint creation during preroute optimization. Checkpoint creation is disabled by default.

-overwrite

If this option is used, then optimization will use the same design name during checkpoint creation. By default, optimization will save each checkpoint design with a different design name. See Section **Description** for more details of the design names.

-prefix *prefix*

This option causes optimization to add a prefix to the design names being saved.

DESCRIPTION

By enabling checkpointing using the `set_checkpoint_strategy` command, optimization will save the design (snapshot) at periodic intervals. This allows the user to examine the intermediate results while optimization is still proceeding.

By default, each checkpoint design will be given a different design name (cell name). The design names (cell name) are of the form:

`<command>_checkpoint_<design_name>_<timestep>_<number>`

where `<command>` is either "place_opt" or "clock_opt", `<design_name>` is the name of the design (the internal name seen by the tool), `<timestep>` is the timestamp when `<command>` is run, and `<number>` is a sequential number starting from "1" and is incremented each time a checkpoint is created.

Since a user may want to make multiple runs, the timestamps allow a user to know which designs relate to which run. The timestamp is of the form `yyymmdd_hhmmss`.

If the `-prefix` option is used, then the design names are of the form:

`<prefix>_<command>_checkpoint_<design_name>_<timestep>_<number>`

If the `-overwrite` option is used, then the design name becomes

```
<command>_single_checkpoint_<design_name>_<timestampl>_<number>
```

where the same name is being used, unless it is currently being accessed.

Each time a checkpoint is to be created, the tool will generate a checkpoint design name, and check if the design is currently being used (created from previous runs). If the design is not currently being used, then the tool will use the same name and replace the old design with the new checkpoint design. If the design is currently being used, then the tool will NOT overwrite the design, but will generate a new checkpoint design name.

EXAMPLES

We use the place_opt command as our examples below.

Suppose, prior to place_opt command, we run the command :

```
prompt> set_checkpoint_strategy -enable
```

Then, during place_opt, the tool creates the following checkpoint designs:

```
place_opt_checkpoint_MYDESIGN_080901_120402_1  
place_opt_checkpoint_MYDESIGN_080901_120402_2  
place_opt_checkpoint_MYDESIGN_080901_120402_3  
..., etc.
```

where MYDESIGN is the name of the design, and the timestamp is Sept 1st, 2008, at time 12:04:02.

If, during this run, some of the designs are being accessed, then the next available number will be used. For example, if place_opt_checkpoint_MYDESIGN_080901_120402_2 is currently being accessed, then the checkpoint designs created will be:

```
place_opt_checkpoint_MYDESIGN_080901_120402_1  
place_opt_checkpoint_MYDESIGN_080901_120402_3  
place_opt_checkpoint_MYDESIGN_080901_120402_4  
..., etc.
```

If the user instead had used:

```
prompt> set_checkpoint_strategy -enable -overwrite
```

then the checkpoint designs will be:

```
place_opt_checkpoint_MYDESIGN_080901_120402_1
```

Only this name is used, unless this design is being accessed when the checkpoint is being created, then the next available name will be used:

```
place_opt_checkpoint_MYDESIGN_080901_120402_2
```

If the user had used:

```
prompt> set_checkpoint_strategy -enable -prefix myrun
```

set_checkpoint_strategy

2142

then the checkpoints created will be:

```
myrun_place_opt_checkpoint_MYDESIGN_080901_120402_1  
myrun_place_opt_checkpoint_MYDESIGN_080901_120402_2  
myrun_place_opt_checkpoint_MYDESIGN_080901_120402_3  
..., etc.
```

The user can also use the command `remove_checkpoint_designs` to remove the checkpoint designs created.

SEE ALSO

```

clock_opt(2)  
report_checkpoint_designs(2)  
remove_checkpoint_designs(2)
```

set_chiplevel_pad_physical_constraints

Set chiplevel physical constraints on PAD cells.

SYNTAX

```
status set_chiplevel_pad_physical_constraints
[-dist_left_edge_to_pad float]
[-dist_top_edge_to_pad float]
[-dist_right_edge_to_pad float]
[-dist_bottom_edge_to_pad float]
```

ARGUMENTS

`[-dist_left_edge_to_pad float]`

On the top and bottom die edges, specify minimum distance in microns pads must be placed away from the left die edge. Specified value must be positive floating point type. Default value is 0.

`[-dist_top_edge_to_pad float]`

On the left and right die edges, specify minimum distance in microns pads must be placed away from the top die edge. Specified value must be positive floating point type. Default value is 0.

`[-dist_right_edge_to_pad float]`

On the top and bottom die edges, specify minimum distance in microns pads must be placed away from the right die edge. Specified value must be positive floating point type. Default value is 0.

`[-dist_bottom_edge_to_pad float]`

On the left and right die edges, specify minimum distance in microns pads must be placed away from the bottom die edge. Specified value must be positive floating point type. Default value is 0.

DESCRIPTION

This command allows users to specify minimum distance (in microns) the pads must back-off from the implied die corner. When the design is saved, these constraints are also saved to Milkyway.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to specify the minimum distance for pads.

```
prompt> set_chiplevel_pad_physical_constraints -dist_left_edge_to_pad 50 -  
dist_top_edge_to_pad 50 -dist_right_edge_to_pad 50 -dist_bottom_edge_to_pad 50
```

SEE ALSO

```
remove_io_constraints(2)  
set_pad_physical_constraints(2)  
set_pin_physical_constraints(2)  
write_io_constraints(2)
```

set_clock_gating_check

Puts setup and hold checks on clock gating cells.

SYNTAX

```
int set_clock_gating_check
[-setup setup_margin]
[-hold hold_margin]
[-rise]
[-fall]
[-high | -low]
[object_list]
```

Data Types

<i>setup_margin</i>	float
<i>hold_margin</i>	float
<i>object_list</i>	list

ARGUMENTS

-setup *setup_margin*

Specifies the setup margin for the clock gating signal. For AND and NAND clock gating elements, the setup time is checked relative to the 0->1 transition of the clock input. For OR and NOR gating elements, the setup time is checked against the 1->0 transition of the clock input. For more complicated gating elements, the setup check will be against the clock transition where the clock input goes from a controlling value to a noncontrolling value for the clock gating element.

-hold *hold_margin*

Specifies the hold margin for the clock gating signal. For AND and NAND clock gating elements, the hold time is checked relative to the 1->0 transition of the clock input. For OR and NOR gating elements, the hold time is checked against the 0->1 transition of the clock input. For more complicated gating elements, the hold check will be against the clock transition where the clock input goes from a noncontrolling value to a controlling value for the clock gating element.

-rise

Specifies if rising delays are constrained for clock-gating checks. If you do not specify the **-rise** or **-fall** option, both rising and falling delays are constrained.

-fall

Specifies if falling delays are constrained for clock-gating checks. If you do not specify the **-rise** or **-fall** option, both rising and falling delays are constrained.

-high

Indicates that the check is to be performed on the high level of the clock. By default, timing analysis determines whether to use the high or low level

of the clock using information from the cell's logic. That is, for AND and NAND gates, the check is performed on the high level; for OR and NOR gates, on the low level. For some complex cells (for example, MUX, OR-AND) it cannot be determined which level to use, and thus no check is performed unless either **-high** or **-low** is specified. This option can be used only when the object list contains cells or pins.

-low

Indicates that the check is to be performed on the low level of the clock. By default, timing analysis determines whether to use the high or low level of the clock using information from the cell's logic. That is, for AND and NAND gates, the check is performed on the high level; for OR and NOR gates, on the low level. For some complex cells (for example, MUX, OR-AND) it cannot be determined which level to use, and thus no check is performed unless either **-high** or **-low** is specified. This option can be used only when the object list contains cells or pins.

object_list

Specifies a list of cells, pins, or clock objects where the clock gating setup or hold margins are to be checked. By default, if **object_list** is not specified, the clock gating check is applied to the **current_design**.

It is possible to enable clock gating checks only for selected clock gating cells by specifying the names of the cells in the object list. Clock gating checks for specific cells override any clock gating checks that may have been specified for the design.

Setting clock gating checks on pins can enables clock gating checks only for specific pins.

Setting clock gating checks on clock objects enables checks for all clock gating cells driven by the clock.

It is possible for the user to specify which interval of the clock should the clock gating checks be made by using the **-high** and **-low** option.

DESCRIPTION

The **set_clock_gating_check** command provides the ability to check setup or hold margins for control inputs of clock gating cells. The setup check ensures that the clock gating input stabilizes for a given amount of time before the clock input of the gating cell makes a transition to a noncontrolling value. The hold check ensures that the clock gating signal stabilizes for a given period of time after the clock input has gone back to a controlling value. Together, the two checks ensure that the clock gating signal stabilizes for the entire period of time when the gated clock input has a noncontrolling value. This is so that the gating signal can not "clip" a clock edge or generate spurious clock pulses by changing when the clock input is noncontrolling.

The clock gating checks created by **set_clock_gating_check** act as constraints for the **compile** command, which will try to adjust the delays of the logic driving the clock gating inputs in order to avoid setup or hold violations.

Be aware that the presence of clock gating checks on a clock gating cell disables certain logic transformations that otherwise might be applied to the cell. The **compile** command can adjust only the size of the cell by replacing it with other cells with the same logic function but with different drive capacity. No other logic transformations involving the clock gating cell is permitted.

The **set_clock_gating_check** command can only create setup and hold checks against a clock signal. The command cannot introduce setup or hold checks between two nonclock signals.

To undo **set_clock_gating_check**, use **remove_clock_gating_check**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example creates setup checks with a 0.75 margin and hold checks with a 0.5 margin for all clock gating inputs in current design.

```
prompt> set_clock_gating_check -setup 0.75 -hold 0.5
```

The following example creates setup checks with a 0.58 rise margin for all cells driven by the clock CLK1.

```
prompt> set_clock_gating_check -setup 0.75 -hold 0.5 \
[get_clocks CLK1]
```

The following example creates only a hold check with margin 0.64 on all gating inputs of cell CLK_GATE1.

```
prompt> set_clock_gating_check -hold 0.64 CLK_GATE1
```

The following example creates a setup check with margin 0.44 and a hold check with margin 0.64 on all gating inputs of cell CLK_GATE1, and specifies that the clock is non-controlling when it is low.

```
prompt> set_clock_gating_check -hold 0.64 -low CLK_GATE1
```

`remove_clock_gating_check(2)`
`report_clock(2)`

set_clock_gating_registers

Forces the enabling or disabling of clock gating for specified registers in the current design, overriding all conditions necessary for automatic RTL clock gating by the **compile_ultra -gate_clock** command.

SYNTAX

```
status set_clock_gating_registers
[-include_instances register_list]
[-exclude_instances register_list]
[-undo register_list]
```

Data Types

register_list list

ARGUMENTS

-include_instances register_list

Specifies a list of registers in the current design to be included in clock gating. A register cannot be on more than one of the **-include_instances**, **-exclude_instances**, and **-undo** lists.

-exclude_instances register_list

Specifies a list of registers in the current design to be excluded from clock gating. A register cannot be on more than one of the **-include_instances**, **-exclude_instances**, and **-undo** lists.

-undo register_list

Specifies a list of registers in the current design for which the previous specification to the **set_clock_gating_registers** command is to be undone. A register cannot be on more than one of the **-include_instances**, **-exclude_instances**, and **-undo** lists.

DESCRIPTION

This command specifies registers for which clock gating is to be either enabled or disabled, overriding all conditions necessary for automatic clock gating by the **compile_ultra -gate_clock** command. Registers on the **-include** and **-exclude** lists either receive or do not receive clock gating, regardless of any previous specifications.

Use the **-undo** option to remove the effect of an earlier invocation of the **set_clock_gating_registers** command.

You must run the **set_clock_gating_registers** command before running the **compile_ultra -gate_clock** command; the specifications persist during all subsequent executions of **compile_ultra -gate_clock**. The **set_clock_gating_registers** command directs **compile_ultra -gate_clock** command to implement synchronous load enable flip-flops with gated clocks instead of data feedback through multiplexers if certain conditions (for example, minimum register bank size) are satisfied. This command

overrides these conditions for the specified registers; thus, registers specified by the **-include** option are clock-gated, and registers specified by the **-exclude** option are not clock-gated, regardless of any previously-specified conditions necessary for automatic clock gating.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example excludes the register bank named A_reg in the current design, so that these registers are not clock-gated:

```
prompt> set_clock_gating_registers -exclude_instances A_reg[*]
```

The following example includes the register bank named D_OUT_reg in the MID subdesign, so that this register is always clock-gated:

```
prompt> set_clock_gating_registers -include_instances MID/D_OUT_reg[*]
```

The following example includes and excludes clock gating for registers in the ADDER subdesign:

```
prompt> set_clock_gating_registers \
      -include_instances ADDER/out1_reg[*] \
      -exclude_instances ADDER/out2_reg[*]
```

The following example removes the directive to include and exclude clock gating to and from the registers in the ADDER subdesign:

```
prompt> set_clock_gating_registers \
      -undo {ADDER/out1_reg[*] ADDER/out2_reg[*]}
```

SEE ALSO

`report_clock_gating(2)`

set_clock_groups

Specifies clock groups that are mutually exclusive or asynchronous with each other in a design so that the paths between these clocks are not considered during the timing analysis.

SYNTAX

```
Boolean set_clock_groups
-physically_exclusive
  | -logically_exclusive
  | -asynchronous
[-allow_paths]
[-name name]
-group clock_list
```

ARGUMENTS

-physically_exclusive
Specifies that the clock groups are physically exclusive with each other. Physically exclusive clocks cannot co-exist in the design physically. An example of this is multiple clocks that are defined on the same source pin. The **-physically_exclusive**, **-logically_exclusive** and **-asynchronous** options are mutually exclusive; you must choose only one.

-logically_exclusive
The two types of exclusive clocks are physically exclusive ones and logically exclusive ones. An example of logically-exclusive clocks is multiple clocks, which are selected by a MUX but may have coupling with each other in the design. However, it is not recommended that you set these MUXed clocks to be exclusive if some physical paths exist among them somewhere in the design. The **-physically_exclusive**, **-logically_exclusive** and **-asynchronous** options are mutually exclusive; you must choose only one.

-asynchronous
Specifies that the clock groups are asynchronous to each other. Two clocks are asynchronous with respect to each other if they have no phase relationship at all. Signal integrity analysis uses an infinite arrival window on the aggressor unless all the arrival windows on the victim net and the aggressor net are defined by synchronous clocks. The **-physically_exclusive**, **-logically_exclusive** and **-asynchronous** options are mutually exclusive; you must choose only one.

-allow_paths
Enable the timing analysis between specified clock groups. If this option is not specified, the timing analysis among the defined clock groups are disabled. This option can be used with asynchronous clock groups only.

-name name
Specifies a name for the clock grouping to be created. Each command should specify a unique name, which identifies the exclusive or asynchronous relationship among specified clock groups, and this name is used later on to easily remove the clock grouping defined here. By default, the command

creates a unique name.

-group *clock_list*
Specifies a list of clocks.
You can use the **-group** option more than once in a single command execution. Each **-group** iteration specifies a group of clocks, which are exclusive or asynchronous with the clocks in all other groups. If only one group is specified, it means that the clocks in that group are exclusive or asynchronous with all other clocks in the design. A default other group is created for this single group. Whenever a new clock is created, it is automatically included in this group.
Substitute the list you want for *clock_list*.

DESCRIPTION

Specifies clock groups that are mutually exclusive or asynchronous with each other in a design. The timing paths between these clocks are not considered during timing analysis if **-allow_paths** is not specified. One clock cannot be defined in multiple times during one **set_clock_groups** command execution, but can be included in multiple groups by executing multiple **set_clock_groups** commands.

The two types of exclusive clocks are not treated differently for simple timing analysis. However, signal integrity analysis treats logically exclusive clocks as synchronous for timing windows. The physically exclusive clocks are not considered for timing window analysis with each other.

The paths between these exclusive or asynchronous clocks are not explored during timing analysis unless **-allow_paths** is specified. This is similar to declaring false paths between these clocks. Thus, you do not have to manually set a false path if you have already specified two clocks as exclusive or asynchronous. If a false path is already set between two clocks when you specify that they are exclusive or asynchronous, the false path is overwritten by the **set_clock_groups** command. Other exceptions are unaffected.

When the clocks are asynchronous to each other, the crosstalk analysis ignores the timing relationship between them during the timing window overlap analysis. This scenario is also referred as infinite window overlap. The results can be optimistic without infinite window overlap for the synchronous clocks. Hence it is important that the **set_clock_groups -asynchronous** should be used when the clocks are not synchronous to each other.

A generated clock and its master clock are not in the same group by default when some exclusive or asynchronous clock groups defined. You should put them explicitly in the same group if needed.

If multiple clock groups relationship is defined for the same pair of clocks, physically exclusive has the highest precedence followed by asynchronous and logically exclusive in that order.

To undo the **set_clock_groups** command, use the **remove_clock_groups** command. To report the clock groups defined in a design, use the **report_clock** command with the **-groups** option.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example defines two asynchronous clock domains.

```
prompt> set_clock_groups -asynchronous -name g1 -group CLK1 -group CLK2
```

The following example defines a clock named *CLK1* as asynchronous with all other clocks in a design.

```
prompt> set_clock_groups -asynchronous -group CLK1
```

The following example shows how to simultaneously analyze multiple clocks per register without manually specifying false paths. Assume two pairs of mutually-exclusive clocks that are multiplexed:

CLK1 and *CLK2*
CLK3 and *CLK4*.

If each pair of clocks is selected by a different signal, you must execute two **set_clock_groups** commands to simultaneously analyze all four clocks.

```
prompt> set_clock_groups -logically_exclusive -group CLK1 -group CLK2
prompt> set_clock_groups -logically_exclusive -group CLK3 -group CLK4
```

If each pair of clocks is selected by the same signal, you must execute only one **set_clock_groups** command to simultaneously analyze all four clocks.

```
prompt> set_clock_groups -logically_exclusive \
           -group {CLK1 CLK3} -group {CLK2 CLK4}
```

To define clocks *CLK1* and *CLK2* as physically exclusive

```
prompt> set_clock_groups -physically_exclusive \
           -group {CLK1} -group {CLK2}
```

set_clock_latency

Specifies clock network latency.

SYNTAX

```
string set_clock_latency
[-rise]
[-fall]
[-min]
[-max]
[-source]
[-early]
[-late]
[-clock clock_list]
delay
object_list
```

Data Types

<i>clock_list</i>	list
<i>delay</i>	float
<i>object_list</i>	list

ARGUMENTS

-rise

Indicates that **delay** is to apply only to rise clock network latency. By default, **delay** is applied to both rise and fall clock network latency.

-fall

Indicates that **delay** is to apply only to fall clock network latency. By default, **delay** is applied to both rise and fall clock network latency.

-min

Indicates that **delay** is to apply only to minimum clock network latency. By default, **delay** is applied to both minimum and maximum clock network latency.

-max

Indicates that **delay** is to apply only to maximum clock network latency. By default, **delay** is applied to both minimum and maximum clock network latency.

-source

Indicates that **delay** is to apply to clock source latency. By default, **delay** is applied to clock network latency.

-early

Indicates that **delay** is to apply only to early clock source latency. By default, if **-source** is specified, **delay** is applied to both late and early clock source latency.

-late

Indicates that **delay** is to apply only to late clock source latency. By

```

default, if -source is specified, delay is applied to both late and early
clock source latency.

-clock clock_list
    Indicates that delay is applied with respect to the specified clocks. By
    default, delay is applied to all specified objects.

delay
    Specifies the clock latency value.

object_list
    Specifies a list of names of clocks, ports, and pins for which the clock
    latency is to be set.

```

DESCRIPTION

Two types of clock latency can be specified for a design. The clock network latency is the time it takes a clock signal to propagate from the clock definition point to a register clock pin. The rise and fall latencies are the latencies for rising and falling transitions at the register clock pin, respectively. Inversion of the clock waveform, if present in the clock network, is taken into consideration when computing clock network latencies at register clock pins. Clock source latency (also called insertion delay) is the time it takes for a clock signal to propagate from its actual ideal waveform origin point to the clock definition point in the design. It can be used to model off-chip clock latency when a clock generation circuit is not part of the current design. For generated clocks, clock source latency can be used to model the delay from master-clock to generated clock definition point. The **-early** and **-late** options can be used to specify early and late clock source latencies respectively.

If multiple clocks are allowed per object, the clock latency can be specified with respect to each clock with **-clock** option. Different values can be applied, such that the different clock network can have the different clock latencies.

Design Compiler assumes ideal clocking, which means clocks have a specified network latency (from the **set_clock_latency** command) or zero network latency by default. Propagated clock network latency (from the **set_propagated_clock** command) is normally used for post-layout, after final clock tree generation. Ideal clock network latency provides an estimate of the clock tree for pre-layout.

Clock source latency can be specified for ideal or propagated clocks. The total clock latency at a register clock pin is the sum of clock source latency and clock network latency.

If **set_clock_latency** is applied to pins or ports, it affects all register clock pins in the transitive fanout of the pins or ports. Clock source latencies are only allowed on clocks and clock source pins.

To undo **set_clock_latency**, use **remove_clock_latency**.

To see clock network latency and clock source latency information, use **report_clock -skew**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example specifies a rise latency of 1.2 and a fall latency of 0.9 for clock "CLK1".

```
prompt> set_clock_latency 1.2 -rise [get_clocks CLK1]
prompt> set_clock_latency 0.9 -fall [get_clocks CLK1]
```

The next example specifies an early rise and an early fall source latency of 0.8, and a late rise and a late fall source latency of 0.9 for "CLK1".

```
prompt> set_clock_latency 0.8 -source -early [get_clocks CLK1]
prompt> set_clock_latency 0.9 -source -late [get_clocks CLK1]
```

SEE ALSO

```

report_clock(2)
set_clock_transition(2)
set_clock_uncertainty(2)
set_input_delay(2)
set_propagated_clock(2)
```

set_clock_sense

Specifies the clock sense (with respect to the clock source) propagating forward from the specified pins.

SYNTAX

```
string set_clock_sense
[-stop_propagation]
[-positive]
[-negative]
[-
pulse {rise_triggered_high_pulse | rise_triggered_low_pulse | fall_triggered_high_p
ulse | fall_triggered_low_pulse}]
[-clocks clocks]

```

Data Types

<i>clocks</i>	list
<i>pins</i>	list

ARGUMENTS

-stop_propagation

Stops propagation of the specified clocks at the specified pins.

The **-stop_propagation** option cannot be specified with **-positive**, **-negative**, or **-pulse**.

-positive

Propagates only the positive unate paths forward from the specified pins.

The **-positive** option cannot be specified with **-negative**, **-pulse**, or **-stop_propagation**.

-negative

Propagates only the negative unate paths forward from the specified pins.

The **-negative** option cannot be specified with **-positive**, **-pulse**, or **-stop_propagation**.

-pulse {rise_triggered_high_pulse | rise_triggered_low_pulse | fall_triggered_high_pulse | fall_triggered_low_pulse}

ed_high_pulse | fall_triggered_low_pulse}" Specifies the type of pulse clock that is generated from the specified pins.

The **-pulse** option cannot be specified with **-positive**, **-negative**, or **-stop_propagation**.

-clocks *clocks*

Specifies the clocks to which the specified clock sense applies.

If you do not specify this option, the clock sense setting applies to any clock that passes through the specified pins.

pins

Specifies a list of pins on which to set the clock sense.

DESCRIPTION

This command provides the capability to define the clock sense at nonunate points in the clock network (the command is ignored if it is used on a unate point in the clock network). The specified clock sense propagates forward from the specified pins.

If the **-clocks** option is supplied, only the specified clocks are considered. Otherwise, all clocks passing through the specified pins are considered.

Warning messages are issued if the specified sense can not be respected on the specified pins. Hierarchical pins are not supported.

To undo **set_clock_sense**, use the **remove_clock_sense** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example specifies positive unateness for a pin named XOR/Z with respect to clock CLK1.

```
prompt> set_clock_sense -positive -clocks [get_clocks CLK1] XOR/Z
```

The following example specifies a pulse type for a pin named MUX/Z for all clocks.

```
prompt> set_clock_sense -pulse rise_triggered_high_pulse MUX/Z
```

SEE ALSO

`remove_clock_sense(2)`

set_clock_transition

Sets clock transition attributes on clock objects.

SYNTAX

```
int set_clock_transition
    transition
    [-rise | -fall]
    [-min]
    [-max]
    clock_list
```

Data Types

<i>transition</i>	float
<i>clock_list</i>	list

ARGUMENTS

transition

Allows for the value of the desired transition for clock nets directly fanning out to a sequential device clocked by the clock you specified. Express *transition* in the same unit as the technology library used during optimization.

-rise | -fall

Specifies whether the value is applicable for rising or falling transition. If neither is specified, both rising and falling clock transitions are set. If you specify **-rise** or **-fall**, the other transition value is assumed to be 0.0, if an explicit value does not already exist.

-min

Specifies that the value is applicable for minimum delay analysis. If no value is specified for minimum delay analysis, the maximum value is used.

-max

Specifies that the value is applicable for maximum delay analysis. If no value is specified for minimum delay analysis, the maximum value is used.

clock_list

Provides a list of names of clocks in the current design. The transition times on all register clock pins in the transitive fanout of specified clock are affected. Only ideal clocks can be specified in the list. The values are ignored for propagated skews on register clock pins.

DESCRIPTION

This command overrides the calculated transition times on clock pins of registers and associated nets. The **set_clock_transition** command places **clock_rise_transition** and **clock_fall_transition** attributes on the *clock_list*.

This command is especially useful for prelayout when clock trees are incomplete, and because calculated transition times at register clock pins can be pessimistic. The transition value, specified with this command, overrides the transition times of all nets directly feeding a sequential element clocked by the specified clock.

Use this command only with ideal clocks. For propagated clocks, the calculated transition times are used. Set propagated clocks only after the final clock tree is constructed.

For ideal clocks, the calculated transition values are used if no explicit transition times are specified using **set_clock_transition**.

To undo **set_clock_transition**, use the **remove_clock_transition**, **remove_attribute**, or **reset_design** command.

To list all clock transition values that have been set, use **report_clock -skew**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets both rise and fall transition times to 0.75 on clock pins of all sequential elements clocked by *CLK*:

```
prompt> set_clock_transition 0.75 CLK
```

The following example sets only the fall transition time to 0.64 on clock pins of all sequential elements clocked by *CLK*:

```
prompt> set_clock_transition 0.64 -fall CLK
```

The following example sets both rise and fall transition times to 0.0 on clock pins of all sequential elements clocked by a certain clock:

```
prompt> set_clock_transition 0.0 all_clocks()
```

<i>logic_level_number</i>	integer
<i>max_scale_factor</i>	float
<i>min_scale_factor</i>	float
<i>hierarchy_preservation_pin_or_cell</i>	string

ARGUMENTS

-float_pin_max_delay_rise *max_delay_rise_value*

Specifies the maximum rising-edge-induced delay from the float pin to its end pin (the longest path). This option should be used in combination with the **-float_pins** option. The time unit is the same as the library unit.

-float_pin_min_delay_rise *min_delay_rise_value*
Specifies the minimum rising-edge-induced delay from the float pin to its end pin (the shortest path). This option should be used in combination with the **-float_pins** option. The time unit is the same as the library unit.

-float_pin_max_delay_fall *max_delay_fall_value*
Specifies the maximum falling-edge-induced delay from the float pin to its end pin (the longest path). This option should be used in combination with the **-float_pins** option. The time unit is the same as the library unit.

-float_pin_min_delay_fall *min_delay_fall_value*
Specifies the minimum falling-edge-induced delay from the float pin to its end pin (the shortest path). This option should be used in combination with the **-float_pins** option. The time unit is the same as the library unit.

-float_pins *float_pin_collection*
Specifies a collection of input pins to be set as float pins. A float pin is a synchronous pin whose delay is user-specified. A float exception can overwrite stop exception on a pin. If you use this option, you should also specify at least one of the **-float_pin_max_delay_rise**, **-float_pin_min_delay_rise**, **-float_pin_max_delay_fall**, and **-float_pin_min_delay_fall** options.

-stop_pins *stop_pin_collection*
Specifies a collection of input pins to be set as stop pins. A stop pin is a synchronous pin whose phase delay is 0.

-non_stop_pins *non_stop_pin_collection*
Specifies a collection of input pins to be set as non-stop pins. These are pins that clock tree synthesis treats as sinks, with some exceptions like implicit exclude pins. Currently, the tool does not support the specifying of a non-stop pin exception for hierarchical pins and boundary ports. Specifying a non-stop exception on a pin that has an already-existing stop, float exception, or exclude exception, overwrites the previous exception.

-exclude_pins *exclude_pin_collection*
Specifies a collection of input pins that the **set_clock_tree_exceptions** command is to set as exclude pins. An exclude exception can overwrite a stop or float exception on a pin.

-dont_touch_subtrees *dont_touch_pin_collection*
Specifies a collection of input pins that the **set_clock_tree_exceptions** command is to set as dont_touch_subtree pins.

-dont_buffer_nets *collection_or_list_of_nets*
Specifies clock nets that are not to be buffered during clock tree synthesis. You can use this option to prevent clock tree synthesis from inserting cells on specified nets. It can be used in conjunction with a configuration file. The **optimize_clock_tree** command also honors this attribute and does not insert delay cells on the specified nets. The primary use of this option is to preserve the subtree structure for later runs of synthesis.

-dont_size_cells *collection_or_list_of_cells*
Specifies clock tree cells that can be moved but cannot be sized during clock tree synthesis and optimization.

```

-size_only_cells collection_or_list_of_cells
    Specifies the clock tree cells that can only be sized but not moved during
    clock tree synthesis and optimization.

-float_pin_logic_level logic_level_number
    Specifies the logic level to be set for those float pins defined by the -
    float_pins option. This option should be used in combination with the -
    float_pins option. The default value is 0 if you do not use the -
    float_pin_logic_level option when you define a float pin.

-max_float_pin_scale_factor max_scale_factor
    Specifies a scale factor that should be applied to float pin delays. This
    scale factor applies for the maximum operating condition of the currently
    active multicorner-multimode scenario. Setting a value of 1.0 implies no
    scaling. See further information in the DESCRIPTION section.

-min_float_pin_scale_factor min_scale_factor
    Specifies a scale factor that should be applied to float pin delays. This
    scale factor applies for the minimum operating condition of the currently
    active multicorner-multimode scenario. Setting a value of 1.0 implies no
    scaling. See further information in the DESCRIPTION section.

-preserve_hierarchy hierarchy_preservation_pin_or_cell
    Specifies a collection of cells, pins, or hierarchy instances for which
    boundary needs to be preserved.

```

DESCRIPTION

This command sets the following types of exceptions: float pins, stop pins, nonstop pins, exclude pins, dont_touch_subtree pins, dont_buffer nets, dont_size cells, and size_only cells.

Float Pins

A float pin is a user-defined timing model that describes a delay as seen from a pin. If you expect that a float pin is to be rising edge, you should specify max_rise and min_rise delay. If you expect it to be falling edge, you should specify max_fall and min_fall delay. If you expect it to be both rising and falling edge, you should specify all 4 delays: max_rise, min_rise, max_fall, and min_fall. Float pins are used in the following situations:

- To define the data setup requirements for hard macros. For example, if a clock signal terminates on a RAM pin that has significant setup requirements, you might want to synthesize the clock tree so that the arrival time of the clock signal at the RAM occurs before the arrival time of the clock signal at the sequential clock sinks. The float pin alerts the clock tree synthesis engine that there is additional internal delay within the RAM.
- To provide a coarse model of the internal clock network delays inside a hierarchical block that is timing-arc-based timing modeled. (For example, one that is using STAMP, ETM, QTM, or a Library Compiler format.) If the internal clock network is already implemented, use the timing arcs between the clock pins and the dedicated internal clock pins to model the internal clock delays. This technique

allows you to properly reflect the sensitivity of the internal clock delays to the input clock transition delay.

- To capture the budgeted clock network delays of a portion of the current clock network that will be implemented separately. In this case, define the float pin as the input pin of the subtree root cell. If the subtree is already implemented, use the **-dont_touch_subtrees** option instead.

Stop Pins

A stop pin is an explicitly specified end pin of a clock tree. Unlike default clock sinks, a stop pin can be the input pin of a nonsequential cell. Clock tree synthesis treats a stop pin as a clock sink.

Clock tree synthesis minimizes skew up to the specified stop pin. The tool ignores any insertion delay in the transitive fanout between the stop pin and a default clock sink.

Clock tree synthesis determines the active edge of a stop pin from the timing arcs of the corresponding library cell. Usually, an input pin of a combinational cell is sensitive to both the rising edges and the falling edges. To override stop pin edge sensitivity and set a rising edge stop pin, use the following format:

```
set_clock_tree_exceptions -float_pins <pin_name> -float_pin_max_delay_rise 0 -  
float_pin_min_delay_rise 0. To set a falling edge stop pin, use:  
set_clock_tree_exceptions -float_pins <pin_name> -float_pin_max_delay_fall 0 -  
float_pin_min_delay_fall 0.
```

Exclude Pins

An exclude pin is a clock sink whose timing is not important. Excluding a pin from the clock tree removes individual default clock sinks or branches of a clock tree. Clock tree synthesis does not calculate skew and insertion delay for the excluded clock sinks or branches. Similarly, the **report_clock_tree** command does not consider exclude pins in the skew calculations.

don't_touch_subtree Pins

A dont_touch_subtree pin does not change the set of a sink that requires balancing, but it forces the **compile_clock_tree** command to maintain an existing part of a clock tree "as is." A dont_touch_subtree pin is used when two clock networks share part of some clock logic behind a multiplexer.

During clock tree synthesis, no modifications (such as buffering, clock net routing, attribute setting, or back-annotation) occur on any of the clock tree nets in the transitive fanout of a dont_touch_subtree pin. You must ensure that the transitive fanout of the dont_touch_subtree pin is properly synthesized. If some nets in the transitive fanout have not been properly buffered and back-annotated, the post-layout correlation of clock tree delays are likely to be poor. The other types of clock tree exceptions are supported in the transitive fanout of the dont_touch_subtree pin.

The **report_timing** command does not take into account clock-tree exceptions. For

instance, the **report_timing** command reports that clock network path delays are going through combinational clock gates bearing an exclude pin exception.

Scaling float pin delays in multiple corners

For multicorner clock optimization and reporting, you should set a "float pin scale factor" for each scenario of interest. Setting the scale factor simultaneously balances clocks across different process and temperature corners. The scale factor is applied to all float pin delays in the design. Set it by using the **-max_float_pin_scale_factor** and **-min_float_pin_scale_factor** options. Setting a value of 1.0 implies no scaling.

When multicorner-multimode scenarios are in use and scale factors are not set, the **report_clock_tree** command issues a warning, and the tool performs no scaling. This might result in misleading reports. If you do not provide scale factors, multicorner clock optimization (performed by the **optimize_clock_tree** command) automatically fills them in. After multicorner optimization is complete, you can safely report clock delays in all corners used for optimization. Note that multicorner clock optimization sets scale factors only for scenarios that are active when the tool runs the **optimize_clock_tree** command.

Preserve hierarchy for pin, cell, or hierarchy instances

Specifies a list of pin, cell, or hierarchy instances for which boundary will be preserved. There is neither new port punch nor port renaming for the specified instances.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The examples in this section are on based on the following scenario.

- A clock tree named CLK1 has been defined to begin at a pin of one of the I/O pads, with fanout to three child hierarchical blocks named Reg_block, Mult_block, and Viterbi_block. The precompiled clock tree of the Viterbi_block port cannot be altered.
- Timing analysis shows that the delay of the precompiled clock tree from the Viterbi_block/CLK port to the first end pin is 0.33nS and the delay to the last end point is 0.52nS.

The following example defines the Viterbi_block/CLK clock input port as a float pin.

```
prompt> set_clock_tree_exceptions\
-float_pin_max_delay_rise 0.52\
-float_pin_min_delay_rise 0.33\
-float_pins [get_pins Viterbi_block/CLK]
```

The following example defines a RAM pin named Mult_block/RAM0/EN as a float pin. The internal setup requirement for the RAM is 0.12ns.

```
prompt> set_clock_tree_exceptions\
-float_pin_max_delay_fall 0.12\
-float_pin_min_delay_fall 0.12\
-float_pins [get_pins Mult_block/RAM0/EN]
```

The following example explicitly defines sink pins. The original clock tree has in place intermediate combinational logic pins named U1_AND02/IN1 and U1_AND02/OUT before some of the implicit sequential sink pins.

```
prompt> set_clock_tree_exceptions\
-stop_pins [get_pins U1_AND02/IN1]
```

The following example removes two sink pins from skew examination during subsequent synthesis of the clock tree.

```
prompt> set_clock_tree_exceptions\
-exclude_pins [get_pins UReg_1/CLK UReg_2/CLK]
```

The following example prevents the cell CLKBUFX1_G1B1I1 from being resized.

```
prompt> set_clock_tree_exceptions\
-dont_size_cells {CLKBUFX1_G1B1I1}
```

Alternatively, you can use a collection of cell instances as the argument to the **-dont_size_cells** option:

```
prompt> set_clock_tree_exceptions\
-dont_size_cells [get_cell CLKBUFX1_G1B1I1]
```

The following example specifies the cell CLKBUFX1_G1B1I1 cell for cell sizing only.

```
prompt> set_clock_tree_exceptions\
-size_only_cells {CLKBUFX1_G1B1I1}
```

Alternatively, you can specify a collection of cell instances for cell sizing only.

```
prompt> set_clock_tree_exceptions\
-size_only_cells [get_cell CLKBUFX1_G1B1I1]
```

In the following example, the clock tree has intermediate combinational logic pins named U1_AND02/IN1 and U1_AND02/OUT. The U1_AND02/IN1 pin traces through several registers that do not need skew examination. This example removes from examination during clock tree synthesis the branch that begins at U1_AND02/IN1 and ends at sequential pins.

```
prompt> set_clock_tree_exceptions\n-exclude_pins [get_pins U1_AND02/IN1]
```

The following example sets scale factors for float pins in different multicorner-multimode scenarios.

```
prompt> current_scenario scenario1\nprompt> set_clock_tree_exceptions\n-max_float_pin_scale_factor 1.0\n-min_float_pin_scale_factor 0.6\nprompt> current_scenario scenario2\nprompt> set_clock_tree_exceptions \n-max_float_pin_scale_factor 0.9\n-min_float_pin_scale_factor 0.5
```

The following example defines hierarchy preservation exception on hierarchy cell reg_g2.

```
prompt> set_clock_tree_exceptionsfp\n-preserve_hierarchy [get_cells reg_g2]fp
```

SEE ALSO

```

Data Types

<i>clock_name_or_collection</i>	collection
<i>corner_values</i>	string

ARGUMENTS

-clock_trees *clock_name_or_collection*

Specifies a set of clocks to be processed. Only clock names defined through `create_clock` or `create_generated_clock` are accepted. If there is a list of clock names, the options then apply to those clocks only. By default, the options apply for all the clocks.

-enable_multicorner_optimization {none | all | corner_spec}

Specifies a type of multicorner optimization to the command. This option applies to all clocks in the design, and cannot be specified together with "`-clock_trees clock_name_or_collection`". The valid values are one of **none**, **all**, or **corner_spec**, a corner specification (described below). The default value is **none**.

When **none** is specified, optimization considers only the max corner in the current MCMM scenario.

When **all** is given, optimization both the min and max corners of all currently active MCMM scenarios.

When **corner_spec** is used, optimization will look only at the specified corners. The specified corner may be from inactive MCMM corners, if you wish.

-corner_target_skew *corner_values*

Sets target skews for selected process corners. This setting overrides the setting of the `-target_skew` option of the `set_clock_tree_options` command. For corners that are not specified, the value from the `-target_skew` option of the `set_clock_tree_options` command will be used. If that value is not specified, the zero will be used. See below for details on the format of the corner values.

You can use `-corner_target_skew` to set a target value for RC-skew by using the special corner name "rc". If you do not set this value, the tool will select an appropriate value for you -- based on your technology and other

skew targets.

-gate_sizing true | false
 Enables or disables gate sizing. The valid value is **true** or **false**, default is true. The gates in question are the user instantiated gates and buffers only and not introduced cells during compile_clock_tree or optimize_clock_tree; Compile_clock_tree or optimize_clock_tree introduced cells can always be sized, with the exception of boundary cells. User gates, for example, are those that are introduced during prior to compile_clock_tree, or user may have put them for some purpose. By default, gate_sizing is **true**.

-gate_relocation true | false
 Enables or disables gate relocation; The valid value is **true** or **false**, default is true. The gates in question are the user instantiated gates and buffers only and not introduced cells during compile_clock_tree or optimize_clock_tree; Compile_clock_tree or optimize_clock_tree introduced cells can always be relocated. User gates, for example, are those that are introduced prior to compile_clock_tree, or user may have put them for some purpose. By default, gate_relocation is **true**.

-area_recovery true | false
 Controls optimization via area recovery; The valid value is **true** or **false**, default is **true**. Area recovery will improve clock tree area/power, without degrading insertion delay or skew.

-preserve_levels true | false
 Preserves levels. The valid value is **true** or **false**. Default is false. If set to true, then the number of levels will be preserved. This option is combining delay insertion and delay removal options. The target_early_delay, if specified with set_clock_tree_options, will override preserve_levels only at the root of the clock. By default, preserve_levels is **false**.

-relax_insertion_delay true | false
 Adds insertion delay of the clock tree. The valid value is **true** or **false**. Default is false. If set to true, then the insertion delay of the clock tree is increased approximately 10% over the minimum possible value. The added insertion delay allows area/power to be improved -- sometimes significantly.

-balance_rc true | false
 Equalizes the RC delay between different clock paths. The valid value is **true** or **false**. Default is false. If set to true, then optimization is done to help equalize the RC delay between wildly different clock paths. Buffers at the root of clock paths that cover short distances will be relocated so that the RC delay is closer to that of long paths. In general, this optimization adds relatively little wire, and it improves overall skew in many process and temperature corners.

DESCRIPTION

This command is the UI setting options for clock tree optimization in the tool. Before command optimize_clock_tree or clock_opt, user can use this command to set options to specific clocks if -clock_trees is given, or set options to the design which will be applied to all clocks that do not have the per clock option.

Enabling multi-corner optimization and defining appropriate MCMM scenarios, will cause `optimize_clock_tree` to perform multi-corner optimization. The user can also use this command to enable or disable some of the other processing steps of `optimize_clock_tree`.

This command only sets options for `optimize_clock_tree`. In `clock_opt`, `compile_clock_tree` and `optimize_clock_tree` are called. This `set_clock_tree_optimization_options` only affect `optimize_clock_tree` part of `clock_opt`.

Options `-gate_sizing`, `-gate_relocation` are both under `set_clock_tree_options` and `set_clock_tree_optimization_options`. If they are under `set_clock_tree_optimization_options`, they control `optimize_clock_tree`; if under `set_clock_tree_tree_options`, they control optimization during `compile_clock_tree`. Under `set_clock_tree_options`, there are `-buffer_sizing/-buffer_relocation/-delay_insertion`. They also only control `compile_clock_tree`.

Specifying corners for optimization

The `-enable_multicorner_optimization` option of `set_clock_tree_optimization_options` turns on multicorner clock tree optimization if you use the "all" value or use a corner specification. The corner specification selects process/temperature/voltage corners from defined MCMM scenarios that should be to optimize clocks.

Each MCMM has two corners, referred to as "max" and "min". In each corner, you may define a operating condition (PVT) specification and a parasitic specification. The operating condition is set up using the `set_operating_conditions` command. The parasitic information comes from the `set_tlu_plus_files` command.

Additionally, the tool timing engine requires you to draw an association between the cell library used in the max corner and the cell library used in the min corner. Traditionally, this was done with the `set_min_library` command. Instead, we will suggest that users leverage the newer and more robust `set_scaling_lib_group` command. It is possible to define scaling groups which contain only one library. And once the scaling groups are defined, you can use them without restriction in any scenario.

It is important to note that `optimize_clock_tree` can optimize in multiple corners. However, it does not address multiple modes. The clock tree mode behavior is based on a single "cts scenario". By default, the cts scenario is the "current" scenario as set by the `current_scenario` command. You can override this default with the `set_cts_scenario` command. Other scenarios will only be used for there PVT and wire information.

If you choose to optimize your clock using only selected MCMM corners, you need to provide a corner specification to the `-enable_multicorner_optimization` option of `set_clock_tree_optimization_options`. The format of a corner specification is a space-separated string of corners. Each corner is a scenario name, followed by a colon (:), followed by "max" or "min". So if you wanted to select the max corner of scenario1 and the min corner of scenario2, you would use

```
"scenario1:max scenario2:min"
```

Additionally, you can use the special scenario name called "default". The default scenario is always defined to be the same as the "cts scenario" (see above). Using

```
"default" is also useful if you have not defined any scenarios. In this case,  
"default" refers to the corners defined for non-MCMM optimization.
```

```
"default:max default:min"
```

You should note that the max corner of the cts scenario is always used as the first corner in multicorner clock optimization. It is not possible to turn off optimization of this corner. This first corner is treated specially, and should represent the slowest gates and slowest wires of any corner. This will give you the best optimization results.

Specifying corner values for optimization

The -corner_target_skew option of set_clock_tree_optimization_options requires a "corner_values" argument. This argument is similar to the corner specification in the previous section, except that each corner is followed by an equal sign (=) and a floating point value. So if you want to set the target skew of corner scenario1:max to 0.050, and corner scenario1:min to 0.030, then you would specify:

```
"scenario1:max=0.05 scenario2:min=0.030"
```

You can use -corner_target_skew to set a target value for RC-skew by using the special corner name "rc":

```
"rc=0.05"
```

Note there are no spaces between the corner, the equal sign and the floating point value. So the following is incorrect:

```
"scenario1:max = 0.05"      # incorrect
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example disables gate_sizing to clock PCI_CLK.

```
prompt> set_clock_tree_optimization_options\  
  \-clock_trees [get_clock PCI_CLK]\  
  -gate_sizing false  
1
```

This example sets the multicorner optimization type to "all" for all clocks.

```
prompt> set_clock_tree_optimization_options\  
  -enable_multicorner_optimization all
```

This example sets the multicorner optimization type to work on two selected corners.

```
prompt> set_clock_tree_optimization_options\
-enable_multicorner_optimization "scenario1:max scenario2:min"
```

This example sets corner-specific target skews, and also sets a target for RC-skew.

```
prompt> set_clock_tree_optimization_options\
-corner_target_skew "scenario1:max=0.100 scenario2:min=0.050 rc=0.050"
```

[-operating_condition string]
```

ARGUMENTS

-clock_trees *clock_name_or_collection*

Specifies a set of clocks to be processed. Only clock names defined through `create_clock` or `create_generated_clock` are accepted. If there is a list of clock names, the options then apply to those clocks only. By default, the options apply for all the clocks.

-layer_list *list_of_layer_names*

Specifies the list of layers that can be used during routing of clock nets. If the list has more than 2 elements, the min and max will be derived by the program.

-target_early_delay *minimum_insertion_delay*

Specifies the minimum insertion delay constraint as `minimum_insertion_delay` for this clock tree. If specified, the clock tree synthesis engine first attempts to build an optimized clock tree and if the insertion delay (of the longest path) of this clock tree is smaller than the specified value, add a chain of buffer as needed to meet this delay. By default, target early delay is 0.

-target_skew *desired_skew*
 Specifies the desired value for maximum skew as *desired_skew* for this clock tree. Once this skew target is met, the optimization will concentrate more on other QOR goals (such as insertion delay, area and power). The default value is 0.

-max_capacitance *max_capacitance_value*
 Sets maximum capacitance design rule checking (DRC) constraints for the buffers and inverters used while compiling the specified clock tree. This value takes precedence over the *max_capacitance* constraint set on the design as well as over the one coming from the library, but can be overridden on all instances of specific types of buffers and inverters in the clock tree by specifying a different value for this constraint on the **set_clock_tree_references** command line. The clock tree root cell and occasional gating cells present on the clock network are not impacted by the **set_clock_tree_references** DRC constraints unless they are instances of buffers or inverters with overridden DRC constraints. By default, max capacitance is 0.6 (pf).

-max_transition *max_transition_value*
 Sets maximum transition design rule checking (DRC) constraints for the buffers and inverters used while compiling given clock tree. This value takes precedence over the *max_transition* constraint set on the design as well as over the one coming from the library, but can be overridden on all instances of specific types of buffers and inverters in the clock tree by specifying a different value for this constraint on the **set_clock_tree_references** command line. The clock tree root cell and occasional gating cells present on the clock network are not impacted by the **set_clock_tree_references** DRC constraints unless they are instances of buffers or inverters with overridden DRC constraints. By default, max transition is 0.5 (ns).

-max_fanout *max_fanout_value*
 Sets maximum fanout design rule checking (DRC) constraints for the buffers and inverters used while compiling given clock tree. This value takes precedence over the *max_fanout* constraint set on the design as well as over the one coming from the library, but can be overridden on all instances of specific types of buffers and inverters in the clock tree by specifying a different value for this constraint on the **set_clock_tree_references** command line. The clock tree root cell and occasional gating cells present on the clock network are not impacted by the **set_clock_tree_references** DRC constraints unless they are instances of buffers or inverters with overridden DRC constraints. By default, max fanout is 2000.

-max_buffer_levels *number_of_levels_value*
 Specifies the maximum number of levels that can be used for buffering a clock net. If the receiving pins have different phase delay, the value will automatically be relaxed (increased) so that the number of buffer levels between the driver of the net and the receiving pin with the largest phase delay satisfies user-specified value. By default, max buffer levels is 0.

-max_rc_delay_constraint *max_rc_delay_value*
 Specifies the maximum RC delay constraint from a driver pin to each receiver pin while compiling the given clock tree. This option is mutually exclusive with **-max_rc_scale_factor** option (see below). By default, this max RC delay constraint is disabled.

-max_rc_scale_factor *scale_factor_of_internal_derived_rc_delay*
 Enables the maximum RC delay constraint by specifying a scale factor while compiling the given clock tree. The true RC delay constraint is determined from multiplying this scale factor by an internal derived RC delay. This option is mutually exclusive with **-max_rc_delay_constraint** option (see above). By default, this scale factor is unset and the max RC delay constraint is disabled.

-routing_rule *name_of_the_non_default_routing_rule*
 Specifies the nondefault routing rule to be used for clock tree nets.

-use_default_routing_for_sinks *n*
 Forces the default routing rule to be used on the leaf nets that drive the clock tree sinks, and nets at the bottom *n*-1 levels of the clock tree. A net is considered as leaf net if it drives at least one flip-flop or latch. Float pins, exclude pins and dont_touch_subtree pins are treated as non-sink pins of the clock tree for this purpose. For example, a net that drives only one float pin will not be treated as leaf net for this purpose. The default is 0. This option is only active if the **-routing_rule** option is specified.

-buffer_relocation true | false
 Enables and disables buffer relocation during clock tree optimization. By default, buffer relocation is true.

-buffer_sizing true | false
 Enables and disables buffer sizing during clock tree optimization. By default, buffer sizing is true.

-gate_relocation true | false
 Enables and disables gate relocation during clock tree optimization. By default, gate relocation is true.

-gate_sizing true | false
 Enables and disables gate sizing during clock tree optimization. By default, gate sizing is false.

-delay_insertion true | false
 Enables and disables delay insertion during clock tree optimization. By default, delay insertion is false.

-logic_level_balance true | false
 Build the clock tree with balanced logic level. By default, logic level balance is false.

-ocv_clustering true | false
 Enables OCV-aware register clustering for capturing timing-critical endpoints, to improve clock path sharing between the relatively more timing-critical register pairs. Any previous setups, that can affect the timing measured between register pairs (such as **set_clock_latency** and **set_clock_uncertainty**), may affect clustering criteria, and accordingly affect resulting clock trees. By default, ocv clustering is false.

-config_file_read *filename*
 Build the clock tree according to the configuration specified.

```

-config_file_write filename
    Dump out the clock tree configuration after synthesis.

-insert_boundary_cell true | false
    Insert boundary cells near clock input ports for block-level designs. By
    default, insert boundary cell is false.

```

DESCRIPTION

The general flow for synthesizing a clock tree is as follows:

1. Create the initial clock tree (**set_clock_tree_options**). Based on the results, proceed to step 2 below, if needed.
2. Define clock tree exceptions (**set_clock_tree_exceptions**).
3. Specify the buffers to use in the synthesis of the clock tree (**set_clock_tree_references**).
4. Synthesize the clock tree and update the design netlist with the legal placement results (**compile_clock_tree**).

The **set_clock_tree_options** command traces the specified net and creates or modifies the structure that is input to the clock tree synthesis engine.

A clock tree structure is defined from a pin of an instance called the source pin. It is assumed that the clock tree is to be constructed from this source pin until leaf pins of sequential elements are encountered. Exceptions are used to modify this assumption. After clock tree exceptions have been added or modified, you can synthesize the clock tree.

At the minimum, specify the source pin of the clock tree to create an initial clock tree structure. (If source pin is not specified, the command defines the settings for all clock trees in the design.) Once you have created the definition of the clock tree, other clock tree commands use the same source pin to do one or more of the following to the clock tree:

- Add constraints to it
- Add exceptions to it
- Report on it
- Synthesize it

The **root** option defines the pin that is the root, or starting point, of the clock tree. It must be a pin of a leaf cell or input port of the top level design. Hierarchical ports are not supported as clock tree sources.

The **set_clock_tree_references** command specifies the library buffers to use for clock tree synthesis.

Tracing Rules

The following section assumes that you are familiar with the concepts of timing arcs, timing arc unateness, combinational arcs, and sequential arcs. The following set of rules is applied to determine which clock tree nets in the transitive fanout

of the driving pin are buffered, and which load pins of those nets are considered as balance points during clock tree synthesis. The general rule is to gather a set of clock tree nets by iteratively tracing through cells in the clock network. Tracing starts at the net driven by the root pin and continues through the owning cells of its load pins when they meet the following conditions:

- The output pin has at least one fanout.
- The output pin is not on a pad net, which is a net between an I/O pad cell and a top-level port, such as a bonding net.
- There is at least one combinational timing arc between the input pin on the clock path and the output pin or there is a sequential clock-to-output data arc and the related output is the source of a generated clock.
- There is no three-state enable or disable timing arc between the input pin on the clock path and the output pin.

If more than one output on a cell meets these conditions, clock tree synthesis selects a random pin and generates a warning message that notifies you of the choice. Use the **set_disable_timing** command to disable as many unwanted timing arcs in the cell as needed to force a specific output pin to be selected. When both sequential arcs (to generated clock source pins) and combinational arcs can be traced, additional warning messages are issued.

When clock tree synthesis traces through a cell to an output pin, the driven net becomes a clock tree net and the rules are iteratively applied to all its load pins to determine the other clock tree nets among the transitive fanout of this net.

Clock tree synthesis does not trace through a clock posedge arc, a clock negedge arc, or a three-state enable arc. All other combinational cell timing arcs are traced through. This includes timing arcs of multiplexer cells or combinational arcs from data pins of latch cells (transparent mode). Sequential clock gating cells are also traced through if there is a combinational arc connected to the clock path. By default, all nonclock pins of sequential elements, except three-state enable or disable pins, become exclude pins unless they have an explicit stop pin exception. For example, the following types of pins are implicitly excluded:

- Pins of combinational cells without fanout
- Pins of combinational cells with disabled timing arcs
- Top-level output ports
- Input pins of pad cells
- Data pins of flip flops or memories

The **-exceptions** option of **report_clock_tree** reports implicitly excluded pins as inferred.

Applying the **set_clock_tree_exceptions** command with appropriate options to some pins in the transitive fanout of the clock root modifies this default behavior.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the examples below, a new clock tree structure is created and modified.

The following example set a target_skew only for the clock_tree of "my_clock".

```
prompt> set_clock_tree_options \
           -clock_trees my_clock -target_skew 0.050
```

The following example adds an exception to exclude a fanout pin Reg0/CP from examination for skew optimization and analysis:

```
prompt> set_clock_tree_exceptions -exclude_pins [get_pins Reg0/CP]
```

The following example adds an exception to define pin Ram0/we as a float pin.

```
prompt> set_clock_tree_exceptions -float_pins [get_pins RAM0/we]
```

The following example reports the current definition of the CLK1 clock tree:

```
prompt> report_clock_tree -clock_trees CLK1
```

The following example creates a clock tree with top-level port CLK1 as the root pin and specifies Inv5 as the reference for the buffer level next to the deepest one, Buf2 for the deepest level, and Buf67 for all other buffer levels. You must also run the **set_clock_tree_references** command to define these specified references for the clock tree. The order of those two commands is irrelevant.

```
prompt> set_clock_tree_options \
           -root [get_ports CLK1] -references_per_level {Buf67 * Inv5 Buf2}
prompt> set_clock_tree_references -clock_trees CLK1 \
           -references {Buf1 Inv7 Buf67 Inv5 Buf2}
```

```

set_clock_tree_references

Specifies the buffers and inverters that can be used in clock tree synthesis.

SYNTAX

```
status set_clock_tree_references
      -references references
      [-sizing_only]
      [-delay_insertion_only]
      [-boundary_cell_only]
```

ARGUMENTS

- references *references*
Specifies the list of buffers and inverters to be used in the clock tree construction.
- sizing_only
Limits usage of specified references for sizing only.
- delay_insertion_only
Limits usage of specified references for delay insertion only.
- boundary_cell_only
Limits usage of specified references for boundary cell insertion only.

DESCRIPTION

This command specifies the buffers and inverters to be used for clock tree synthesis. Specifying several references gives the clock tree algorithm flexibility in the construction of the clock tree and generally provides improved clock tree results.

You can invoke the **set_clock_tree_references** command several times for the same clock tree. Each time you invoke it, any new references it specifies are added to existing references it has previously defined in the construction of the clock tree. That is, each time you use the command, references are only added to the allowed list for a clock tree. The references currently defined on a given clock tree can be seen using **report_clock_tree** command. Use the **reset_clock_tree_references** command to delete the references currently defined for a clock tree.

Currently, references defined using this command are not persistent. This might change in future releases.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example designates library buffers to be used in the synthesis of all clocks of current design.

```
prompt> set_clock_tree_references -references buffer4x
```

SEE ALSO

`set_clock_tree_options(2)`
`set_clock_tree_exceptions(2)`
`compile_clock_tree(2)`

set_clock_uncertainty

Specifies the uncertainty (skew) of specified clock networks.

SYNTAX

```
string set_clock_uncertainty
[object_list
 | -from from_clock
 | -rise_from rise_from_clock
 | -fall_from fall_from_clock
-to to_clock
 | -rise_to rise_to_clock
 | -fall_to fall_to_clock]
[-rise]
[-fall]
[-setup]
[-hold]
uncertainty
```

Data Types

object_list	list
from_clock	list
rise_from_clock	list
fall_from_clock	list
to_clock	list
rise_to_clock	list
fall_to_clock	list
uncertainty	float

ARGUMENTS

object_list

Specifies a list of clocks, ports, or pins for simple uncertainty; the uncertainty is applied either to capturing latches clocked by one of the clocks in *object_list*, or capturing latches whose clock pins are in the fanout of a port or pin specified in *object_list*. You must specify either the pair of **-from** and **-to**, or *object_list*; you cannot specify both.

-from from_clock

This option specifies the source clocks for interclock uncertainty. You must specify either the pair of **-from/-rise_from/-fall_from** and **-to/-rise_to/-fall_to**, or *object_list*; you cannot specify both.

-rise_from rise_from_clock

Same as the **-from** option, but indicates that *uncertainty* applies only to rising edge of the source clock. You can use only one of the **-from**, **-rise_from**, or **-fall_from** options.

-fall_from fall_from_clock

Same as the **-from** option, but indicates that *uncertainty* applies only to falling edge of the source clock. You can use only one of the **-from**, **-rise_from**, or **-fall_from** options.

rise_from, or **-fall_from** options.

-to to_clock
This option specifies the destination clocks for interclock uncertainty. You must specify either the pair of **-from/-rise_from/-fall_from** and **-to/-rise_to/-fall_to**, or *object_list*; you cannot specify both.

-rise_to rise_to_clock
Same as the **-to** option, but indicates that *uncertainty* applies only to rising edge of the destination clock. You can use only one of the **-to**, **-rise_to**, or **-fall_to** options.

-fall_to fall_to_clock
Same as the **-to** option, but indicates that *uncertainty* applies only to falling edge of the destination clock. You can use only one of the **-to**, **-rise_to**, or **-fall_to** options.

-rise
Indicates that *uncertainty* applies to only the rising edge of the destination clock. By default, the uncertainty applies to both rising and falling edges. This option is valid only for interclock uncertainty, and is now obsolete. Unless you need this option for backward-compatibility, use **-rise_to** instead.

-fall
Indicates that *uncertainty* applies to only the falling edge of the destination clock. By default, the uncertainty applies to both rising and falling edges. This option is valid only for interclock uncertainty, and is now obsolete. Unless you need this option for backward-compatibility, use **-fall_to** instead.

-setup
Indicates that *uncertainty* applies only to setup checks. By default, *uncertainty* applies to both setup and hold checks.

-hold
Indicates that *uncertainty* applies only to hold checks. By default, *uncertainty* applies to both setup and hold checks.

uncertainty
A floating point number that specifies the uncertainty value. Typically, clock uncertainty should be positive. Negative uncertainty values are supported for constraining designs with complex clock relationships. Setting the uncertainty value to a negative number could lead to optimistic timing analysis and should be used with extreme care.

DESCRIPTION

Specifies the clock uncertainty (skew characteristics) of specified clock networks. This command can specify either interclock uncertainty or simple uncertainty. For interclock uncertainty, use the **-from/-rise_from/-fall_from** and **-to/-rise_to/-fall_to** options to specify the source clock and the destination clock; all paths between these receive the uncertainty value. For simple uncertainty, use *object_list*; the uncertainty value is either to capturing latches clocked by one of the clocks in *object list*, or capturing latches whose clock pins are in the fanout

of a port or pin specified in *object_list*.

Set the uncertainty to the worst skew expected to the endpoint or between the clock domains. You can increase the value to account for additional margin for setup and hold.

When you specify interclock uncertainty, ensure that you specify it for all possible interactions of clock domains. For example, if you specify paths from CLKA to CLKB and CLKB to CLKA you must specify the uncertainty for both even if the values are the same. For an example, see the EXAMPLES section.

Interclock uncertainty is more specific than simple uncertainty. If a command that specifies interclock uncertainty conflicts with a command that specifies simple uncertainty, the command that specifies interclock uncertainty takes precedence. For an example, see the EXAMPLES section.

If there is no applicable interclock uncertainty for a path, the value for simple uncertainty is used. For an example, see the EXAMPLES section.

To remove the uncertainties set by **set_clock_uncertainty**, use the **remove_clock_uncertainty** command.

To view clock uncertainty information, use the **report_clock -skew** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example specifies that all paths leading to registers or ports clocked by CLK have setup uncertainty of 0.65 and hold uncertainty of 0.45.

```
prompt> set_clock_uncertainty -setup 0.65 [get_clocks CLK]
prompt> set_clock_uncertainty -hold 0.45 [get_clocks CLK]
```

The following example specifies interclock uncertainties between PHI1 and PHI2 clock domains.

```
prompt> set_clock_uncertainty 0.4 -from PHI1 -to PHI1
prompt> set_clock_uncertainty 0.4 -from PHI2 -to PHI2
prompt> set_clock_uncertainty 1.1 -from PHI1 -to PHI2
prompt> set_clock_uncertainty 1.1 -from PHI2 -to PHI1
```

The following example specifies interclock uncertainties between PHI1 and PHI2 clock domains with specific edges.

```
prompt> set_clock_uncertainty 0.4 -rise_from PHI1 -to PHI2
```

```
prompt> set_clock_uncertainty 0.4 -fall_from PHI2 -rise_to PHI2
prompt> set_clock_uncertainty 1.1 -from PHI1 -fall_to PHI2
```

The following example shows conflicting **set_clock_uncertainty** commands, one for simple uncertainty and one for interclock uncertainty. The interclock uncertainty value of 2 takes precedence.

```
prompt> set_clock_uncertainty 5 [get_clocks CLKA]
prompt> set_clock_uncertainty 2 \
    -from [get_clocks CLKB] -to [get_clocks CLKA]
```

The following example specifies the uncertainty from CLKA to CLKB and from CLKB to CLKA. Notice that both must be specified even though the value is the same for both.

```
prompt> set_clock_uncertainty 2 \
    -from [get_clocks CLKA] -to [get_clocks CLKB]
prompt> set_clock_uncertainty 2 \
    -from [get_clocks CLKB] -to [get_clocks CLKA]
```

The following example illustrates a situation in which simple uncertainty is used when there is no applicable interclock uncertainty for a path. The first command specifies a simple uncertainty of 5 for CLKA paths, and the second command specifies an interclock uncertainty of 2 for paths from CLKB to CLKA. If there are paths between CLKA and other clocks (for example, CLKC, CLKD, ...) for which interclock uncertainty has not been specifically defined, the simple uncertainty (in this case, 5) is used.

```
prompt> set_clock_uncertainty 5 [get_clocks CLKA]
prompt> set_clock_uncertainty 2 \
    -from [get_clocks CLKB] -to [get_clocks CLKA]
```

report_clock(2)
set_clock_latency(2)
set_clock_transition(2)
```

set_combinational_type

Sets attributes on cell instances to specify which combinational cells from the target library are to be used by **compile**.

SYNTAX

```
int set_combinational_type  
-replacement_gate replacement_gate  
[cell_list]
```

Data Types

<i>replacement_gate</i>	string
<i>cell_list</i>	list

ARGUMENTS

-replacement_gate *replacement_gate*
Specifies a combinational gate from the target_library to use by **compile** as the exact replacement gate for the cells in the cell list. Sets **combinational_type_exact** to the *replacement_gate* on all cells in *cell_list*. This argument is required.

cell_list
Specifies a list of cells in which to use the replacement combinational gate.

DESCRIPTION

The **set_combinational_type** command specifies replacement combinational gate information for **compile** to use by setting attributes on the cell instances. Specifying **-replacement_gate** sets the **combinational_type_exact** attribute to *replacement_gate*, indicating to use this attribute as the replacement gate for those cells.

In the mapping process for combinational gates, **compile** attempts to convert combinational gates tagged by **set_combinational_type** to the specified replacement combinational gate. In the absence of attributes on a combinational cell instance to control the mapping, **compile** chooses the one best for timing, power, or area.

After mapping the cell instances to the replacement gate, **compile** sets the **dont_touch** attribute on these cell instances to disable further optimization on these cells.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example indicates that the replacement combinational gate for cell U1 is cell AN2P. This sets the **combinational_type_exact** attribute to 'AN2P' on the cell 'U1'. The presence of this attribute indicates that cell 'U1' attempts an exact mapping to gate 'AN2P'.

```
prompt> set_combinational_type -replacement_gate AN2P U1
```

set_congestion_options

Sets options for congestion optimization.

SYNTAX

```
int set_congestion_options
[-max_util value]
[-layer name]
[-availability value]
[-coordinate {X1 Y1 X2 Y2}]
```

Data Types

<i>value</i>	float
<i>name</i>	string

ARGUMENTS

-max_util value
Specifies the maximum utilization factor.

-layer name
Specifies the layer name whose availability is reduced.

-availability value
Specifies the availability of the routing resource for the layer

-coordinate {X1 Y1 X2 Y2}
Specifies the lower left and upper right coordinates for which the congestion options will apply. The numbers are in microns.

DESCRIPTION

The **set_congestion_options** command sets congestion options for the current design. Congestion occurs because the number of wires going through a region exceeds the capacity of that region. If the ratio of usage-to-capacity is larger than 1, the region is congested.

The **-max_util** option specifies how densely the tool can pack cells in uncongested regions to remove congestion in congested regions. You should set this variable based on how much placeable area is needed. The default maximum utilization is 0.95.

The **-layer** and **-availability** options specify how much of the routing resource for the given layer is available to be used. For example, in a design whose M5 and M6 will be 70% occupied by future P/G routing, you can set the availability of M5 and M6 to be 0.30. This means even if currently there is no route in M5 and M6, we will consider them to be 70% full. If you don't want to use M5 and M6 for signal routing at all, you can use **set_ignored_layer** to mark them as ignored. However, it is still desired to specify the availability in this case, because we still need to know the existence of these future nets to perform a good estimation on the coupling effects of them.

Congestion options can be design-wide or regional. If the **-coordinate** option is not specified, the values are design wide. If **-coordinate** option is specified, the values will only be applied to the bounding box specified by with the option. Regional congestion options will be assigned an ID, which can be used to report or remove the regional options.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **set_congestion_options** command.

```
prompt> set_congestion_options -layer METAL5 -availability 0.5
prompt> set_congestion_options -layer METAL5 -availability 0.7 \
    -coordinate {0 0 10 10}
prompt> set_congestion_options -layer METAL5 -max_util 0.9
```

SEE ALSO

report_congestion_options(2)
report_congestion(2)
set_ignored_layers(2)
```

set_connection_class

Sets the connection class value on ports.

SYNTAX

```
status set_connection_class
connection_class_value
object_list
```

Data Types

<i>connection_class_value</i>	string
<i>object_list</i>	list

ARGUMENTS

connection_class_value

Specifies the desired *connection_class* value of ports contained in *object_list*. The *connection_class_value* is a single string value. This string can contain any number of space-separated connection classes (see the example below).

object_list

Specifies ports whose connection classes are set.

DESCRIPTION

Connection classes are placed on ports of designs in a technology library by using Library Compiler. The **set_connection_class** command places the *connection_class* attribute on ports of designs being optimized (such as the current design). This is used to indicate a connection class requirement for the network that is connected to the specified port.

The "connection class" label is an attribute that is used to describe connection requirements for a given technology. Only those loads and drivers with the same connection class label can be legally connected. The labels "universal" and "default" are reserved labels. The "universal" label indicates that a pin or port can legally connect with any other load or driver. The "default" label is used for those library pins that do not otherwise have a connection class assigned to them through any library attributes. For designs being optimized, the "universal" label is assigned to those ports that do not otherwise have a connection class assigned to them. To change the default connection class label for those ports, use the variable **default_port_connection_class**.

The connection requirements specified using connection classes are treated as Design Rule Constraints by the Design Compiler. Optimization attempts to build designs that meet connection class requirements even at the expense of other constraints on the design (such as area or power).

To view connection class values on ports, use the **report_port** or **get_attribute** command. To see the default connection class value for a library, use the **report_lib**

command. To check your design for connection class violations, use the **check_design** command. To reset a connection class value, use the **remove_attribute** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets a connection class "internal" to the port named "xyz" in the current design:

```
prompt> set_connection_class internal xyz
```

The following example sets the connection classes "internal" and "external" on the port "out" in the design "test":

```
prompt> set_connection_class "internal external" test/out
```

In the following example, the connection class on a port is removed:

```
prompt> remove_attribute [get_ports xyz] connection_class
```

`default_port_connection_class(3)`
`target_library(3)`

set_context_margin

Specifies the margin by which to tighten or relax constraints.

SYNTAX

```
string set_context_margin
[-percent]
[-relax]
[-min]
[-max]
value
[object_list]
```

Data Types

value	float
object_list	list

ARGUMENTS

-percent	Indicates that the specified value is a percentage of the delay.
-relax	Relaxes the constraint.
-min	Specifies the margin for minimum constraints.
-max	Specifies the margin for maximum constraints.
value	Determines the margin in absolute value or percentage value.
object_list	Specifies a list of cells or pins.

DESCRIPTION

The **set_context_margin** command specifies a margin to add to or to subtract from input and output delay values when the values are generated by the **allocate_fp_budgets** command. The margin can be specified as an absolute value or as a percentage of the constraint.

The constraints are created using the **characterize** or **allocate_fp_budgets** command.

By default, the input and output delays are adjusted so that they are more constraining. This means that the specified margin is added to the maximum delay values and subtracted from the minimum delay values. If you specify the **-relax** option, the margin is subtracted from the maximum delay values and added to the

minimum delay values.

The margin applies to the current design when no object list is specified. When determining the margin for a pin, the value set for the pin is used. If you do not specify a value for the pin, the value set for the parent cell is used. If neither value is set, the value set for the current design is used. If no margin is specified, the default value is 0.0

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command adds a margin of 0.5 to all maximum values of input and output delay constraints and subtracts the margin from all minimum values of input and output delay constraints. The margin applies to all objects in the current design.

```
prompt> set_context_margin 0.5
```

The following command relaxes (or reduces) the maximum value input delays on *I2/IN* by 10 percent:

```
prompt> set_context_margin -relax -max -percent 10.0 I2/IN
```

SEE ALSO

```

allocate_fp_budgets(2)  
write_script(2)
```

set_cost_priority

Sets the `cost_priority` attribute to a specified value on the current design.

SYNTAX

```
int set_cost_priority
[-default]
[-delay]
cost_list
[-design_rules]
[-min_delay]
```

Data Types

cost_list list

ARGUMENTS

```
-default
    Removes the cost_priority attribute so that the compile command uses its
    default priority.

-delay
    Specifies that max_delay has higher priority than the max design rules.

cost_list
    Specifies a list of costs in decreasing order of priority, selected from the
    following: max_delay, min_delay, max_transition, max_fanout,
    max_capacitance, cell_degradation, and max_design_rules.

-design_rules
    Specifies that max_design_rules cost has higher priority than the max delay
    cost.

-min_delay
    Specifies that min_delay has higher priority than the max_delay, but lower
    priority than max design rules.
```

DESCRIPTION

The **set_cost_priority** command sets the `cost_priority` attribute on the current design. This attribute changes the precedence that **compile** uses when different constraints conflict with each other. For example, by default the design rule **max_transition** has priority over **max_delay**, meaning that if both constraints cannot be met, **compile** fixes the transition violation at the expense of delay.

If a list of costs is given, any costs that are not in the list are assumed to follow afterwards in their default relative priority.

If **set_cost_priority** is specified more than once on a design, the most recent setting is used and the earlier values are removed.

To undo **set_cost_priority**, use the **-default** option, the **remove_attribute** command, or the **reset_design** command.

Use the **report_constraints** command to obtain a summary of the constraints of the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the priority so that design rule violations are not fixed if they increase max delay cost:

```
prompt> set_cost_priority -delay
```

The following example sets the priority so that **max_fanout** and **max_capacitance** have higher priority than delay, but **max_transition** and **cell_degradation** have lower priority:

```
prompt> set_cost_priority {max_fanout max_capacitance max_delay}
```

SEE ALSO

```

```

set_critical_range

Sets the **critical_range** attribute to a specified value on a list of designs.

SYNTAX

```
int set_critical_range  
range_value designs
```

Data Types

<i>range_value</i>	float
<i>designs</i>	list

ARGUMENTS

range_value
Specifies the value to which the **critical_range** attribute is to be set.

designs
Indicates the list of designs to which the **critical_range** attribute applies.

DESCRIPTION

Sets the **critical_range** attribute to *range_value* on the designs in **designs**.

The **compile** command uses the **critical_range** attribute of the top-level design as the default critical range for path groups that do not have a critical range set. If you do not set the **critical_range** attribute, such path groups get a critical range of 0.0. You can assign critical range values to individual path groups with the **group_path -critical_range** command.

Critical range specifies a margin of delay for path groups in optimization. This must be a positive float number or 0.0. A critical range of 0.0 means that only the most critical paths (the ones with the worst violation) are optimized. If you specify a nonzero critical range, near-critical paths within that amount of the worst path will also be optimized if possible.

To undo **set_critical_range**, use **remove_attribute** or **reset_design**.

To show the critical range values for each path group, use **report_path_group**. To show the critical range cost of the design, use **report_constraint**.

For some backward compatibility, if **compile** is run on a design with no **critical_range** attribute and the obsolete variable **compile_default_critical_range** is set, the attribute is created and set to the same value on the design. The attribute always has precedence over the variable setting. If **compile** is run when the attribute exists and has a different value than the variable, a warning is printed that the variable is being ignored. Consequently, if the value for critical range optimization has to be changed between two **compile** commands on the same design, the **set_critical_range** command must be used since changes to the **compile_default_critical_range** variable after the first compile will be ignored.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the default critical range value for design "top" to be 10.0.

```
prompt> set_critical_range 10.0 top
```

set_cts_batch_mode

Enables clock tree synthesis batch mode.

SYNTAX

```
status set_cts_batch_mode
```

ARGUMENTS

None.

DESCRIPTION

To reduce runtime in script that call CTS commands many times, in some cases, one clock at a time, this command turns on the batch mode. It skips CTS pre and post process whenever it can. For example, if 3 compile_clock_tree commands are called, the first call will run the CTS pre-process, but skipped the post process. The second and the third calls will skip both pre and post process. The following command, like reset_cts_batch_mode, save_mw_cel or other trigger commands will make up the CTS post process.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
set_cts_batch_mode  
compile_clock_tree -clock_trees clk1  
compile_clock_tree -clock_trees clk2  
  
report_cts_batch_mode  
optimize_clock_tree  
balance_inter_clcok_delay  
reset_cts_batch_mode
```

SEE ALSO

```
reset_cts_batch_mode(2)  
report_cts_batch_mode(2)
```

set_cts_scenario

Sets the specified scenario as the clock tree synthesis scenario.

SYNTAX

```
string set_cts_scenario
[scenario_name]
```

Data Types

scenario_name string

ARGUMENTS

scenario_name

Specifies the name of the scenario to be marked as the clock tree synthesis scenario.

DESCRIPTION

This command sets the specified scenario as the clock tree synthesis scenario and returns the name of the clock tree synthesis scenario. The scenario must exist before you run this command. In the multicorner-multimode (MCM) flow, the **compile_clock_tree**, **optimize_clock_tree**, and **balance_inter_clock_delay** commands work on the clock tree synthesis scenario (if defined), or on the current scenario if the clock tree synthesis scenario is not defined.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following example uses **set_cts_scenario** to set the clock tree synthesis scenario:

```
prompt> create_scenario MODE1
prompt> set_cts_scenario MODE1
MODE1
prompt> get_cts_scenario
MODE1
prompt> remove_cts_scenario
1
prompt>get_cts_scenario

prompt>
```

SEE ALSO

`balance_inter_clock_delay(2)`
`clock_opt(2)`
`compile_clock_tree(2)`
`get_cts_scenario(2)`
`optimize_clock_tree(2)`
`remove_cts_scenario(2)`

set_current_command_mode

SYNTAX

```
string set_current_command_mode
-mode command_mode | -command command
```

Data Types

<i>command_mode</i>	string
<i>command</i>	string

ARGUMENTS

-mode *command_mode*

Specifies the name of the new command mode to be made current. **-mode** and **-command** are mutually exclusive; you must specify one, but not both.

-command *command*

Specifies the name of the command whose associated command mode is to be made current. **-mode** and **-command** are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **set_current_command_mode** sets the current command mode. If there is a current mode in effect, the current mode is first cancelled, causing the associated clean up to be executed. The initialization for the new command mode is then executed as it is made current.

If the name of the given command mode is empty, the current command mode is cancelled and no new command mode is made current.

A current command mode stays in effect until it is displaced by a new command mode or until it is cleared by an empty command mode.

If the command completes successfully, the new current command mode name is returned. On failure, the command returns the previous command mode name which will remain current and prints an error message unless error messages are suppressed.

EXAMPLES

The following example sets the current command mode to a mode called "mode_1"

```
prompt> set_current_command_mode -mode mode_1
```

The following example clears the current command mode without setting a new mode.

```
prompt> set_current_command_mode -mode ""
```

The following example sets the current command mode to the mode associated with the command "modal_command"

```
prompt> set_current_command_mode -command modal_command
```

set_data_check

Sets data-to-data checks using the specified values of setup and hold time.

SYNTAX

```
string set_data_check
-from from_object
| -rise_from from_object
| -fall_from from_object
-to to_object
| -rise_to to_object
| -fall_to to_object
[-setup | -hold]
[-clock clock_object]
[check_value]
```

Data Types

<i>from_object</i>	object
<i>to_object</i>	object
<i>clock_object</i>	object
<i>check_value</i>	float

ARGUMENTS

-from *from_object*

Specifies a pin or port in the current design as the related pin of the data-to-data check to be set. Both rising and falling delays are checked. You must specify one of **-from**, **-rise_from**, or **-fall_from**.

-rise_from *from_object*

Similar to the **-from** option, but applies only to rising delays at the related pin. You must specify one of **-from**, **-rise_from**, or **-fall_from**.

-fall_from *from_object*

Similar to the **-from** option, but applies only to falling delays at the related pin. You must specify one of **-from**, **-rise_from**, or **-fall_from**.

-to *to_object*

Specifies a pin or port in the current design as the constrained pin of the data-to-data check to be set. Both rising and falling delays are constrained. You must specify one of **-to**, **-rise_to**, or **-fall_to**.

-rise_to *to_object*

Similar to the **-to** option, but applies only to rising delays at the constrained pin. You must specify one of **-to**, **-rise_to**, or **-fall_to**.

-fall_to *to_object*

Similar to the **-to** option, but applies only to falling delays at the constrained pin. You must specify one of **-to**, **-rise_to**, or **-fall_to**.

```

-setup
    Indicates that the data check value is for setup analysis only. If neither -setup nor -hold is specified, the value applies to both setup and hold.

-hold
    Indicates that the data check value is for hold analysis only. If neither -setup nor -hold is specified, the value applies to both setup and hold.

-clock clock_object
    Specifies the name of a single clock that launches the signal for related pin of the data check.

check_value
    Specifies the value of the setup and/or hold time for the check.

```

DESCRIPTION

The **set_data_check** command specifies a data-to-data check to be performed between the from object and to object using the specified setup and/or hold value.

The pulse relation between clocks of related pin and constrained pin is considered to be zero cycles. The normal sequential check uses one cycle. Data check on clock pin is not supported.

The data check is treated as non-sequential; that is, the path goes through the related and constrained pins and is not broken at these pins. To report the constraint related to the data check, use **report_timing -to data_check_constrained_pin**.

To remove information set by **set_data_check**, use the **remove_data_check** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example creates a data-to-data check from and1/B to and1/A with respect to the rising edge of signal at and1/B, using a setup and hold time of 0.4.

```
prompt> set_data_check -rise_from and1/B -to and1/A 0.4
```

The following example creates a data-to-data check from and1/B to and1/A with respect to the rising edge of signal at and1/B, coming from the clock domain of CK1, constraining only the falling edge of signal at and1/A, using a setup time of 0.5 and no hold check.

```
prompt> set_data_check -rise_from and1/B -fall_to and1/A -setup \
-clock [get_clock CK1] 0.5
```

SEE ALSO

set_default_drive

Sets the default driving strength for specified objects, to be used by Top-Down Environmental Propagation (TDEP).

SYNTAX

```
status set_default_drive
[-min]
[-max]
[-rise]
[-fall]
[-none]
[resistance]
[cell_or_pin_list]
```

Data Types

<i>resistance</i>	float
<i>cell_or_pin_list</i>	list

ARGUMENTS

-min

Indicates that *resistance* is to apply only to minimum resistance.

-max

Indicates that *resistance* is to apply only to maximum resistance. (This is the default if no **-min** or **-max** is specified and also if both options are given.)

-rise

Indicates that *resistance* is to apply only to rise resistance.

-fall

Indicates that *resistance* is to apply only to fall resistance.

-none

Indicates that previous information set by **set_default_drive** is to be removed.

resistance

Specifies the resistance value; allowed values are any nonnegative floating point number.

cell_or_pin_list

Specifies a list of names of cells or pins for which the default driving strength is to be set.

DESCRIPTION

This command specifies a default drive value, to be used later by Top-Down

Environmental Propagation (TDEP).

Note that you can specify both max and min values by issuing two separate commands, one with **-max** and one with the **-min** option. However, if you specify both or none of these two options only the max value will be set and the min value will be removed. To always remove both values use the **-none** option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets default drives and then removes them by using the **-none** option.

```
prompt> set_default_drive -rise 5 U_L1
Performing set_default_drive on cell 'U_L1'.
1
prompt> set_default_drive -rise -min 7 U_L1
Performing set_default_drive on cell 'U_L1'.
1
prompt> set_default_drive -fall 6 U_L1
Performing set_default_drive on cell 'U_L1'.
1
prompt> set_default_drive -fall -min 8 U_L1
Performing set_default_drive on cell 'U_L1'.
1
prompt> set_default_drive -none
1
```

SEE ALSO

```
derive_constraints(2)
set_default_driving_cell(2)
set_default_fanout_load(2)
set_default_load(2)
```

set_default_driving_cell

Sets the default driving cell for specified objects, to be used by Top-Down Environmental Propagation (TDEP).

SYNTAX

```
int set_default_driving_cell
[-lib_cell lib_cell_name]
[-library lib]
[-rise] [-fall]
[-pin pin_name]
[-from_pin from_pin_name]
[-dont_scale] [-no_design_rule]
[-multiply_by factor] [-none]
cell_or_pin_list
```

Data Types

<i>lib_cell_name</i>	string
<i>lib</i>	string
<i>pin_name</i>	string
<i>from_pin_name</i>	string
<i>factor</i>	float
<i>cell_or_pin_list</i>	list

ARGUMENTS

-lib_cell lib_cell_name

Specifies the name of a library cell to be used to drive the ports; both the **driving_cell_rise** and the **driving_cell_fall** string attributes are set to to *lib_cell_name* on the ports. If the cell has more than one output pin, you must also use the **-pin** option. To specify different cells for the rising and falling cases, execute the command twice, once with **-rise** and once with **-fall**, using the appropriate *lib_cell_name* for each.

-library lib

You must use this option with the **-lib_cell** option. Specifies the library in which to find *library_cell_name*. This is either a library name or a collection. By default, the libraries in **link_library** are searched for the cell. To specify different libraries for the rising and falling cases, execute the command twice, once with **-rise** and once with **-fall**, using the appropriate *lib* for each.

-rise

Indicates that the **lib_cell_name**, **lib**, **pin_name**, and **from_pin_name** correspond to the rising case. You can use this option with **-fall** to specify both the rising and the falling case.

-fall

Indicates that the **lib_cell_name**, **lib**, **pin_name**, and **from_pin_name** correspond to the falling case. You can use this option with **-rise** to specify both the rising and the falling case.

-pin *pin_name*
 You must use this option with the **-lib_cell** option. Specifies the output pin on the driving cell that is to drive the ports; needed if the driving cell has more than one output pin, or if the **-from_pin** option is used. The default is to use the first timing arc found on the library cell. To specify different pins for the rising and falling cases, execute the command twice, once with **-rise** and once with **-fall**, using the appropriate *pin_name* for each.

-from_pin *from_pin_name*
 You must use this option with both **-pin** and **-lib_cell**. Specifies the name of the input pin on the driving cell that is to be used when finding a timing arc; needed if the driving cell has more than one input pin on the driving cell and the arcs from those pins have different drive characteristics. The default is to use the first timing arc found on the library cell.

-dont_scale
 You must use this option with the **-lib_cell** option. Indicates that the timing analyzer is not to scale the drive capability of the ports according to the current operating conditions. By default, the port drive capability is scaled for operating conditions exactly as the driving cell itself would have been scaled.

-no_design_rule
 Indicates that the design rules associated with the driving cell are not to be applied to the driven port. Timing-related attributes are still applied. By default, design rule attributes (*max_fanout*, *max_capacitance*, *max_transition*, *min_fanout*, *min_capacitance*, *min_transition*) are derived from the driving cell and its library and applied to the port.

-multiply_by *factor*
 You must use this option with the **-lib_cell** option. Specifies a factor by which to multiply the delay characteristics of the ports; the default is 1.0. Both the load delay and the transition times of the port are affected.

-none
 Delete previous *set_default_driving_cell* info.

cell_or_pin_list
 Specifies a list of names of cells or pins to which the information applies.

DESCRIPTION

This command sets a default driving cell for specified cells or pins; this driving cell will later be used by Top-Down Environmental Propagation (TDEP).

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the default driving cell and then removes it using the **-none** option.

```
prompt>set_default_driving_cell -lib_cell ND2 -library lsi_10k \
-pin Z -from_pin A -rise -dont_scale -mult 2.3;
1
prompt>set_default_driving_cell -lib_cell IVP -library lsi_10k \
-pin Y -from_pin B -fall;
1
prompt>set_default_driving_cell -none;
1
```

SEE ALSO

`derive_constraints(2)`
`set_default_drive(2)`
`set_default_fanout_load(2)`
`set_default_load(2)`

set_default_fanout_load

Sets the default fanout load to be used by Top-Down Environmental Propagation (TDEP) .

SYNTAX

```
status set_default_fanout_load
[-none]
[fanout_load_value]
[cell_or_pin_list]
```

Data Types

<i>fanout_load_value</i>	float
<i>cell_or_pin_list</i>	list

ARGUMENTS

-none

Indicates that previous information set by **set_default_fanout_load** is to be removed.

fanout_load_value

Specifies the fanout load value; allowed values are any nonnegative floating point number.

cell_or_pin_list

Specifies a list of names of cells or pins for which the default fanout load is to be set.

DESCRIPTION

This command specifies a default fanout load value, to be used later by Top-Down Environmental Propagation (TDEP) .

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets a default load and then removes it by using the **-none** option.

```
prompt> set_default_fanout_load 2 U_L1/U10
Performing set_default_fanout_load on cell 'U_L1/U10'.
1
prompt> set_default_fanout_load -none
```

SEE ALSO

`derive_constraints(2)`
`set_default_drive(2)`
`set_default_load(2)`
`set_default_driving_cell(2)`

set_default_input_delay

Sets the value of the input delay as a percentage of the clock period to be assigned during environment propagation.

SYNTAX

```
int set_default_input_delay
[-none]
percent_delay
[cell_or_pin_list]
```

Data Types

<i>percent_delay</i>	float
<i>cell_or_pin_list</i>	collection

ARGUMENTS

-none

Resets any existing default delays.

percent_delay

Specifies the delay as a percentage of the clock period. Substitute the value you want for *percent_delay*.

cell_or_pin_list

Specifies the list of cells or pins on which the input delay is to be set. Substitute the list you want for *cell_or_pin_list*.

DESCRIPTION

Sets the value of the input delay as a percentage of the clock period to be assigned during environment propagation. By default, a value of 30 is globally used. This value can be overridden on a global basis, on a cell by cell basis, or on a pin-by-pin basis. If no arguments are specified, it sets the global default to the new value. The environment propagation first looks for any values set on the pin. If none exists, it looks at the cell of the pin. If none exists, the global default is used.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

`set_default_output_delay(2)`

set_default_load

Sets the default load to be used by Top-Down Environmental Propagation (TDEP).

SYNTAX

```
status set_default_load
[-min]
[-max]
[-pin_load]
[-wire_load]
[-none]
[value]
[cell_or_pin_list]
```

Data Types

<i>value</i>	float
<i>cell_or_pin_list</i>	list

ARGUMENTS

-min

Indicates that *value* is to apply only to minimum capacitance.

-max

Indicates that *value* is to apply only to maximum capacitance. (This is the default if no **-min** or **-max** is specified and also if both options are given.)

-pin_load

Indicates that *value* is to apply only to pin capacitance.

-wire_load

Indicates that *value* is to apply only to wire capacitance.

-none

Indicates that previous information set by **set_default_load** is to be removed.

value

Specifies the capacitance value; allowed values are any nonnegative floating point number.

cell_or_pin_list

Specifies a list of names of cells or pins for which the default load is to be set.

DESCRIPTION

This command specifies a default load value, to be used later by Top-Down Environmental Propagation (TDEP).

Note that you can specify both max and min values by issuing two separate commands,

one with **-max** and one with the **-min** option. However, if you specify both or none of these two options only the max value will be set and the min value will be removed. To always remove both values use the **-none** option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets a default load and then removes it by using the **-none** option.

```
i  
prompt>set_default_load -wire -min 4  
1  
prompt>set_default_load -none  
1
```

SEE ALSO

```
derive_constraints(2)  
set_default_drive(2)  
set_default_driving_cell(2)  
set_default_fanout_load(2)
```

set_default_output_delay

Sets the output delay as a percentage of the clock period to be assigned during environment propagation.

SYNTAX

```
int set_default_output_delay
[-none]
percent_delay
[cell_or_pin_list]
```

Data Types

<i>percent_delay</i>	float
<i>cell_or_pin_list</i>	collection

ARGUMENTS

-none

Reset any existing default delays.

percent_delay

The delay as the percentage of the clock period.

cell_or_pin_list

The list of cells or pins on which the output delay is to be set.

DESCRIPTION

This command sets the value of the output delay as a percentage of the clock period to be used during environment propagation. By default, a value of 30 is used globally. This value can be over-ridden on a global basis, on a cell by cell basis, or on a pin-by-pin basis. If no arguments are specified, it will set the global default to the new value. The environment propagation will first look for any values set on the pin. If none exists, it will look at the cell of the pin. If none exists, the global default will be used.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

`set_default_input_delay(2)`

set_delay_calculation

Defines the delay model used to compute a timing arc delay value for a cell or net.

SYNTAX

```
int set_delay_calculation
[-arnoldi]
[-elmore]
[-clock_arnoldi]
```

ARGUMENTS

-arnoldi

Specifies that the delay calculation must use the accurate Arnoldi-based delay model. If you do not specify this option, the Elmore delay model will be used for net delays and total capacitance will be used for cell delay computation.

-elmore

This is the default behavior. Specifies that the Elmore delay model will be used for net delays and total capacitance will be used for cell delay computation. This option cannot be used with the **-arnoldi** option.

-clock_arnoldi

This specifies the delay calculation to use Arnoldi-based delay models on clock nets in a post-CTS or a post-Route design.

DESCRIPTION

The **set_delay_calculation** command specifies timing calculation models to be used for delay computation. Delays are computed via the Elmore delay model (option '**-elmore**') or the Arnoldi delay model (option '**-arnoldi**') based on parasitics information for nets of the current design. To provide parasitics information you can use **fextract_rc** or **fread_parasitics**. If parasitics information is not provided delays will be computed using the wire-load model.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command removes all annotated delays and specifies Arnoldi-based model to be used for delay calculation.

```
prompt> set_delay_calculation -arnoldi
The following command computes and annotates Elmore delays.
prompt> set_delay_calculation -elmore
```

SEE ALSO

`extract_rc(2)`
`read_parasitics(2)`
`report_delay_calculation(2)`
`report_timing(2)`

set_delay_estimation_options

Sets the parameters that influence preroute delay estimation.

SYNTAX

```
int set_delay_estimation_options
[-min_unit_horizontal_capacitance float]
[-min_unit_vertical_capacitance float]
[-min_unit_horizontal_resistance float]
[-min_unit_vertical_resistance float]
[-max_unit_horizontal_capacitance float]
[-max_unit_vertical_capacitance float]
[-max_unit_horizontal_resistance float]
[-max_unit_vertical_resistance float]
[-min_unit_horizontal_capacitance_scaling_factor float]
[-min_unit_vertical_capacitance_scaling_factor float]
[-min_unit_horizontal_resistance_scaling_factor float]
[-min_unit_vertical_resistance_scaling_factor float]
[-max_unit_horizontal_capacitance_scaling_factor float]
[-max_unit_vertical_capacitance_scaling_factor float]
[-max_unit_horizontal_resistance_scaling_factor float]
[-max_unit_vertical_resistance_scaling_factor float]
[-min_via_resistance float_resistance]
[-max_via_resistance float_resistance]
[-min_via_resistance_scaling_factor float]
[-max_via_resistance_scaling_factor float]
[-default]
```

ARGUMENTS

-min_unit_horizontal_capacitance *float*
Specifies the minimum horizontal capacitance per unit length for delay calculation.

-min_unit_vertical_capacitance *float*
Specifies the minimum vertical capacitance per unit length for delay calculation.

-min_unit_horizontal_resistance *float*
Specifies the minimum horizontal resistance per unit length for delay calculation.

-min_unit_vertical_resistance *float*
Specifies the minimum vertical resistance per unit length for delay calculation.

-max_unit_horizontal_capacitance *float*
Specifies the maximum horizontal capacitance per unit length for delay calculation.

-max_unit_vertical_capacitance *float*
Specifies the maximum vertical capacitance per unit length for delay

calculation.

-max_unit_horizontal_resistance float
Specifies the maximum horizontal resistance per unit length for delay calculation.

-max_unit_vertical_resistance float
Specifies the maximum vertical resistance per unit length for delay calculation.

-min_unit_horizontal_capacitance_scaling_factor float
Specifies the factor that will be multiplied by the minimum horizontal capacitance per unit length before use in delay calculation.

-min_unit_vertical_capacitance_scaling_factor float
Specifies the factor that will be multiplied by the minimum vertical capacitance per unit length before use in delay calculation.

-min_unit_horizontal_resistance_scaling_factor float
Specifies the factor that will be multiplied by the minimum horizontal resistance per unit length before use in delay calculation.

-min_unit_vertical_resistance_scaling_factor float
Specifies the factor that will be multiplied by the minimum vertical resistance per unit length before use in delay calculation.

-max_unit_horizontal_capacitance_scaling_factor float
Specifies the factor that will be multiplied by the maximum horizontal capacitance per unit length before use in delay calculation.

-max_unit_vertical_capacitance_scaling_factor float
Specifies the factor that will be multiplied by the maximum vertical capacitance per unit length before use in delay calculation.

-max_unit_horizontal_resistance_scaling_factor float
Specifies the factor that will be multiplied by the maximum horizontal resistance per unit length before use in delay calculation.

-max_unit_vertical_resistance_scaling_factor float
Specifies the factor that will be multiplied by the maximum vertical resistance per unit length before use in delay calculation.

-min_via_resistance float_resistance
Specifies the minimum via resistance for delay calculation.

-max_via_resistance float_resistance
Specifies the maximum via resistance for delay calculation.

-min_via_resistance_scaling_factor float
Specifies the factor that will be multiplied by the minimum via resistance before use in delay calculation.

-max_via_resistance_scaling_factor float
Specifies the factor that will be multiplied by the maximum via resistance before use in delay calculation.

```
-default
    Resets all per-unit resistance and capacitance scaling factors and all
    resistance and capacitance scaling factors to default values.
```

DESCRIPTION

The **set_delay_estimation_options** command specifies the parameters that influence preroute RC and delay estimation. Typical values for the scaling factors are between 0.5 and 5.0. The unit distance is 1 micron. Specifying **-default** restores all per-unit resistances and capacitances to library-derived values and all the resistance and capacitance scaling factors to 1.0.

The design must be read before applying the delay estimation options using this command.

The scaling factors are scenario aware. When you create a scenario or set a current scenario, you can at the same time create scaling factors using this command for the current scenario.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example runs the **set_delay_estimation_options** command.

```
prompt> set_delay_estimation_options \
      -max_unit_vertical_resistance 0.00004 \
      -min_unit_horizontal_capacitance_scaling_factor 2.0 \
      -min_via_resistance 0.00001 \
      -min_via_resistance_scaling_factor 1.5 \
      -max_via_resistance 0.00002 \
      -max_via_resistance_scaling_factor 1.5
```

SEE ALSO

`report_delay_estimation_options(2)`

set_design_license

Adds license information to the current design and can be used to require a license before a design can be read in.

SYNTAX

```
status set_design_license
[-dont_show references]
[-quiet]
[-limited limited_keys]
regular_keys
```

Data Types

<i>references</i>	list
<i>limited_keys</i>	list
<i>regular_keys</i>	list

ARGUMENTS

<i>-dont_show references</i>	Specifies a list of references that will not be displayed.
<i>-quiet</i>	Specifies that no informational messages will be displayed.
<i>-limited limited_keys</i>	Specifies a list of licenses that provide limited access to the design.
<i>regular_keys</i>	Specifies a list of licenses that provide regular access to the design.

DESCRIPTION

This command adds license information to a design. For more information on licensing designs, please refer to the section on licensing in the DesignWare manual.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In this example, the full license "ADDERS" and the limited license "EVAL" is added to the current design. In addition, **-dont_show** indicates that the design will not become visible until all the existing references are changed.

```
prompt> set_design_license ADDERS\
```

```
-limited EVAL -dont_show "**"
```

SEE ALSO

`list_licenses(2)`

`set_design_license
2222`

set_design_top

Specifies the top-level design instance.

SYNTAX

```
status set_design_top
      instance_name
```

Data Types

instance_name string

ARGUMENTS

instance_name
Specifies the top-level instance in the design.

DESCRIPTION

The **set_design_top** command specifies the top-level design instance. This information is used only by simulation and verification tools.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLE

The following example shows how to use the **set_design_top** command:

```
prompt> set_design_top ALU07
```

set_die_area

Sets the dimensions of the die area.

SYNTAX

```
int set_die_area
    -coordinate {X1 Y1 X2 Y2}
```

ARGUMENTS

-coordinate {X1 Y1 X2 Y2}
Specifies the lower left and upper right coordinates of the rectangular die area. The coordinates are in microns relative to the chip origin.

DESCRIPTION

The **set_die_area** command defines the die area of the chip. It overwrites any previous die area setting. The die area should be larger than the core area of the chip.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to set a rectangular die area with the lower-left corner at coordinates (100,100) and upper-right corner at the coordinates (2000,2000):

```
prompt> set_die_area -coordinate {100 100 2000 2000}
```

SEE ALSO

`get_die_area(2)`

set_direct_power_rail_tie

Sets the **direct_power_rail_tie** attribute on library pins.

SYNTAX

```
int set_direct_power_rail_tie  
lib_pin_list [true | false]
```

ARGUMENTS

`lib_pin_list`

A list of library pins on which the **direct_power_rail_tie** attribute is to be set. If more than one library pin name is specified, they must be enclosed either in quotes or in braces ({}). For more information about object names, refer to the **find** command manual page.

`true | false`

Specifies the value with which to set the **direct_power_rail_tie** attribute. The default is *true*.

DESCRIPTION

Sets the **direct_power_rail_tie** attribute on library pins. If a match is found, a **direct_power_rail_tie** attribute is assigned to the `library_pin(s)`.

If the value of `direct_power_rail_tie` attribute on a library pin is *true*, then all the pins in the design, for which this is the library pin, it won't connect it to a tieoff cell for connecting it to constant signal. Instead, it will keep them connecting to generic constant signals, so that during power routing these pins can be connected directly to power rails.

To remove **direct_power_rail_tie** attribute, use **remove_attribute**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command specifies that the all the **GND** pins of cells with the library cells **leaf_cell** won't be connected to tieoff cells to connect it to a constant signal.

```
prompt> set_direct_power_rail_tie target_lib/leaf_cell/GND
```

SEE ALSO

`report_direct_power_rail_tie(2)`
`remove_attribute(2)`

set_disable_clock_gating_check

Disables the clock gating check for specified objects in the current design.

SYNTAX

```
string set_disable_clock_gating_check
object_list
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of cells and pins for which the clock gating check is to be disabled.

DESCRIPTION

This command disables the clock gating check for specified cells and pins in the current design.

Any cell or pin in the current design or its subdesigns can be disabled. Cells at lower levels in the design hierarchy are specified as *instance1/instance2/cell_name*. Specify pins at lower levels in the design hierarchy as *instance1/instance2/cell_name/pin_name*.

For subdesigns in the hierarchy, specify instance names instead of design names.

When the clock gating checking through a cell is disabled, all gating checks in the cell are disabled. When the checking through a pin is disabled, any gating check is disabled if it uses the disabled pin as a gating clock pin or a gating enable pin.

The compile command adjusts only the size of the cell by replacing it with other cells having the same logic function but with different drive capacity. No other logic transformations involving the clock gating cell are permitted.

To restore gating checks disabled by the **set_disable_clock_gating_check** command, use the **remove_disable_clock_gating_check** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example disable gating checks on the specified cell or pin:

```
set_disable_clock_gating_check
2226
```

```
prompt> set_disable_clock_gating_check an2/z
```

```
prompt> set_disable_clock_gating_check or1
```

SEE ALSO

`remove_disable_clock_gating_check(2)`

set_disable_timing

Disables timing arcs in the current design.

SYNTAX

```
int set_disable_timing
object_list
[-from from_pin_name -to to_pin_name]
[-restore]
```

Data Types

object_list	list
from_pin_name	string
to_pin_name	string

ARGUMENTS

object_list
Specifies a list of cells, pins, ports, library pins, or library cells through which timing is to be disabled. The cells or the cells of pins are set to be size only to leave room for compile to apply sizing on them.

-from from_pin_name
Specifies that arcs only from this pin on the specified cell are to be disabled. The *object_list* must contain only cells if **-from** and **-to** are specified. When used, the **-from** and **-to** options must be specified together.

-to to_pin_name
Specifies that arcs only to this pin on the specified cell are to be disabled. The *object_list* must contain only cells if **-from** and **-to** are specified. When used, the **-from** and **-to** options must be specified together.

-restore
Indicates that the specified arcs are to be restored and not disabled.

DESCRIPTION

The **set_disable_timing** command disables timing through the specified cells, pins, or ports in the current design.

Any cell, pin, or port in the current design or its subdesigns can be disabled. Cells at lower levels in the design hierarchy are specified as *instance1/instance2/cell_name*. Pins at lower levels in the design hierarchy are specified as *instance1/instance2/cell_name/pin_name*. Ports at lower levels in the design hierarchy are specified as *instance1/instance2/cell_name/port_name*.

Library pins and library cells can also be disabled.

Note: For subdesigns in the hierarchy, you must specify instance names instead of design names.

When the timing through a cell is disabled, only those cell arcs that lead to the output pins of the cell are disabled. When the timing through a pin or port is disabled, only those cell arcs that lead to or from that pin or port are disabled.

When the **-from** and **-to** pins are specified, all arcs between these pins on the cell are disabled.

Use **report_lib -timing_arcs** to list the timing arcs for a library cell, and **report_design** to list the disabled arcs in the current design.

To enable the disabled cells, pins, or ports, use **set_disable_timing -restore** or **reset_design**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

In the following example, all timing arcs are disabled that lead to output pins of cells "U2" and "U3" of the current design.

```
prompt> set_disable_timing {U2 U3}
```

In the following example, all timing arcs that lead to output pin "Z" of cell "U5" in the current design are disabled.

```
prompt> set_disable_timing U5/Z
```

In the following example, all timing arcs between pins 'A' and 'Z' on cell U1/U1 in the current design are disabled.

```
prompt> set_disable_timing U1/U1 -from A -to Z
```

In the following example, all timing arcs between pins 'D' and 'Q' on cell FD1 in the library 'my_lib' are disabled. This command disables arcs on a library cell; therefore, all instances of that library cell are affected in any design linked to the same library.

```
prompt> set_disable_timing my_lib/FD1 -from D -to Q
```

SEE ALSO

`current_design(2)`
`remove_attribute(2)`
`report_lib(2)`
`reset_design(2)`

set_distributed_route

Initializes the network for distributing routing jobs.

SYNTAX

```
status set_distributed_route
[-lsf]
[-lsf_advanced bsub_options]
[-jp_disconnect]
[-jp_machines {mname1 mname2 mname3...}]
[-jp_limit {mname0 limit mname1 limit mname2 limit...}]
[-jp_bin {mname1 bin_path mname2 bin_path...}]
[-jp_lib {mname1 lib_path mname2 lib_path...}]
```

Data Types

bsub_options string

ARGUMENTS

-lsf

Selected the option to setup LSF pool for job distributions. Jobs will be run based on default LSF setup. Used JP setup if the option is not selected.

-lsf_advanced *bsub_options*

Users can specify advance options here to management their submitted jobs on LSF. This option is available only if -lsf option is selected.

-jp_disconnect

Disconnect the network. Default is to connect network to local host and specified machines when the network has not yet been connected, and to get the status of each machine when the network has already been set up. This option is not available for LSF run.

-jp_machines {*mname1 mname2 mname3...*}

Lists machine names where users want to connect to. Local host will always be used, which is on default, so there is no needed to specify host machine here. User can specify total up to 16 machines (including host machine). The list will be kept from previous run, and will be overwritten partially by next run. This option is not available for LSF run.

-jp_limit {*mname0 limit mname1 limit mname2 limit...*}

Users can limit the number of CPUs used on each machine. Specified 0 if users do not want this machine to be used. Specified -1 if users want all of the available CPUs on this machine to be used. All available CPUs will be used if this option is off. The option is not available for LSF run.

The machine name must be appeared in -jp_machines option if users try to specify CPU limit by using this option. The limit setting will be ignored if the machine users specified here can not be matched with the name in -jp_machines list. However, if the machine had been connected due to previous run, even though users don't specified it in -jp_machines, all CPUs will be used on that machine.

mname and *limit* must be in pairs. Meaning that machine name is required if users want to limit the CPUs, and each machine name must be followed by the number of CPU limit.

All available CPUs will be used for certain machines that users don't specify the limit.

-jp_bin {*mname1 bin_path mname2 bin_path...*}

bin_path is where the executable files are located. From different machines, it is likely that the paths are completely different. The default is to set current binary on local host machine, so users don't need to set the *bin_path* for local host machine. The current binary will be applied for all if this option is off. The option is not available for LSF run.

The machine name must be appeared in -jp_machines option if users try to specify any binary path by using this option. The *bin_path* setting will be ignored if the machine users specified here can not be matched with the name in -jp_machines list. However, if the machine had been connected due to previous run, even though users don't specified it in -jp_machines, the existing binary will be used on that machine.

mname and *bin_path* must be in pairs. Meaning that machine name is required if users want to setup *bin_path*, and each machine name must be followed by a binary path.

The path of preceding item will be considered for certain machines that users don't specify the *bin_path*.

-jp_lib {*mname1 lib_path mname2 lib_path...*}

The library path is where the working library is located. From different machines, you have to provide this path so that the library can be reached. The default is to set current library on local host machine, so users don't need to set the *lib_path* for local host machine. The current library will be applied for all if this option is off. The option is not available for LSF run.

The machine name must be appeared in -jp_machines option if users try to specify any library path by using this option. The *lib_path* setting will be ignored if the machine users specified here can not be matched with the name in -jp_machines list. However, if the machine had been connected due to previous run, even though users don't specified it in -jp_machines, the existing library will be used on that machine.

mname and *lib_path* must be in pairs. Meaning that machine name is required if users want to setup *lib_path*, and each machine name must be followed by a library path.

The path of preceding item will be considered for certain machines that users don't specify the *lib_path*.

DESCRIPTION

Set up the network and connect local machine as a host to distribute jobs on available CPUs.

No other operation can be executed except for disconnect if network was connected by previous run, or if JP server is up, only if users shut it down before they can modify any option setting.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example is to setup local host machine for distributing jobs on all available CPUs. Current binary and library are used.

```
prompt> set_distributed_route
```

The following example is to setup host machine, genop0023, for running jobs on LSF. The memory limit is set to 3000, and jobs will be run only on specified queue, normal_test.

```
prompt> set_distributed_route -lsf -lsf_advanced {-m "genop0023" \  
-M 3000 -q "normal_test"}
```

The following example is to distribute jobs on all available CPUs of host machine and only one CPU of machine_0. Current binary and library are used for both machines.

```
prompt> set_distributed_route -jp_machines {machine_0} -jp_limit \  
{machine_0 1}
```

The following example is to distribute jobs on two CPUs of host machine (mach_host), one CPU on machine_1, and 3 CPUs on machine_2. Current binary and library are used for host machine. /user1/username/src/bin are used for machine_1 and machine_2. /user1/username/library/design are used for machine_1 and machine_2.

```
prompt> set_distributed_route -jp_machines {machine_1 machine_2} \  
-jp_limit {mach_host 2 machine_1 1 machine_2 3} -jp_bin {machine_1 \  
/user1/username/src/bin} -jp_lib {machine_1 /user1/username/data/library/ \  
design}
```

```
report_distributed_route(2)  
remove_distributed_route(2)  
close_distributed_route(2)
```

set_domain_supply_net

Set the primary power net and primary ground net of an already existing power_domain. This command is supported only in UPF mode.

SYNTAX

```
int set_domain_supply_net  
domain_name  
-primary_power_net supply_net_name  
-primary_ground_net supply_net_name
```

Data Types

domain_name	string
supply_net_name	string

ARGUMENTS

domain_name
Specify the name of the power domain.
If a power domain with the specified name does not exist, in the current scope, this command fails.
The domain_name option is a required option and must be specified.

-primary_power_net supply_net_name
Specify the power net of the power domain.
If a supply net with the specified name does not exist in the current scope, the command fails. If the supply net is not associated with specified power domain, the command fails.
This is a required option and must be specified.

-primary_ground_net supply_net_name
Specify the ground net of the power domain.
If a ground net with the specified name does not exist in the current scope, the command fails. If the ground net is not associated with specified power domain, the command fails.
This is a required option and must be specified.

DESCRIPTION

The *set_domain_supply_net* command enables you to set the primary power net and the primary ground net of a power domain. All extent of the power domain shares the same power/ground supply until explicitly excluded. Here "explicitly excluded" means it is explicitly connected with another supply_net (non primary power/ground supply_net) by command *connect_supply_net*. This command errors out if power domain already has a primary power and ground net.

The supply_net must be created in the same power_domain at first before it could be set as the primary power or ground supply_net. Use command *create_supply_net* to create a supply_net at a specified power_domain.

Command returns 1 on success, returns 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates two supply_net on power_domain PD1, then set them as primary power or ground net.

```
prompt> create_power_domain PD1 -elements INST_1 PD1 prompt> create_supply_net A_VDD  
-domain PD1 A_VDD prompt> create_supply_net A_VSS -domain PD1 A_VSS prompt>  
set_domain_supply_net PD1 -primary_power_net A_VDD -primary_ground_net A_VSS 1
```

SEE ALSO

```
create_power_domain(2)  
create_supply_net(2)  
connect_supply_net(2)
```

set_dont_touch

Sets the **dont_touch** attribute on cells, nets, references, and designs in the current design, and on library cells, to prevent modification or replacement of these objects during optimization.

SYNTAX

```
status set_dont_touch
object_list
[true | false]
```

Data Types

object_list list

ARGUMENTS

object_list
Specifies list of objects (cells, nets, references, designs, and library cells) on which the **dont_touch** attribute is to be set, so that the objects will not be modified or replaced. If more than one object name is specified, each name must be enclosed in quotation marks (" ") or braces ({}).

true | false
Specifies the value with which to set the **dont_touch** attribute. The default is **true**.

DESCRIPTION

This command sets the **dont_touch** attribute on cells, nets, references, designs in the current design, and on library cells, to prevent modification or replacement of these objects during optimization. Setting the **dont_touch** attribute on a hierarchical cell implies "dont_touch" on all cells below it that do not have **dont_touch** set to **false**. Setting the **dont_touch** attribute on a library cell implies "dont_touch" on all instances of that cell. Setting the **dont_touch** attribute on a net implies "dont_touch" only on mapped combinational cells connected to that net. All mapped combinational cells connected to the net must be at the same level of hierarchy. Setting the **dont_touch** attribute on a reference implies "dont_touch" on all cells of that reference during subsequent optimizations of the design.

Setting the **dont_touch** attribute on a design has an effect only when the design is instantiated within another design as a level of hierarchy. In this case, "dont_touch" on the design implies that all cells under that level of hierarchy are "dont_touch." Setting **dont_touch** on the top-level design has no effect because it is not instantiated within any other design.

Note the following information:

- The **dont_touch** attribute applied by the tool on the cells and nets in the transitive fanout of **dont_touch_network** objects overrides the **false dont_touch**

attribute value that is set by the **set_dont_touch** command. You can see the **dont_touch** value on cells or nets by using the **report_cell** or **report_net** command.

When an object name is specified, the **set_dont_touch** command first looks within the current design for a cell that matches that name. If it finds a match, a **dont_touch** attribute is assigned to that cell. If no match is found, the command next looks within the current design for a net that matches the specified name. If a match is found, a **dont_touch** attribute is assigned to that net. If no match is found, the command next looks for a reference, then a design in the system, and finally for a library cell in the system. The tool assigns a **dont_touch** attribute to the first object for which it finds a match.

To remove the **dont_touch** attribute, use the **remove_attribute** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies that the cells named *block1* and *analog1* are not to be modified during optimization:

```
prompt> set_dont_touch [get_cells {block1 analog1}]
```

The following example specifies that the net named *N1* is not to be modified during optimization:

```
prompt> set_dont_touch [get_nets N1] true
```

The following example specifies that the net named *N1* can be modified during optimization. Setting **set_dont_touch** to **false** removes the previous **dont_touch**.

```
prompt> set_dont_touch [get_nets N1] false
```

SEE ALSO

set_dont_touch_network

Sets the **dont_touch_network** attribute on clocks, pins, or ports in the current design to prevent cells and nets in the transitive fanout of the **set_dont_touch_network** objects from being modified or replaced during optimization.

SYNTAX

```
status set_dont_touch_network
object_list
[-no_propagate]
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of clocks, pins, or ports in the current design on which to set the **dont_touch_network** attribute. If you include more than one object, they must be enclosed in either quotation marks or braces ({}).

-no_propagate

Indicates that the dont_touch network is not propagated through logic gates.

DESCRIPTION

This command sets the **dont_touch_network** attribute on clocks, pins, or ports in the current design. When a design is optimized, the **compile** command assigns **dont_touch** attributes to all cells and nets in the transitive fanout of **dont_touch_network** objects so that they are not modified or replaced during optimization. A **dont_touch** attribute assigned by the tool using the **set_dont_touch_network** command overrides the **FALSE dont_touch** attribute value from the **set_dont_touch** command. To see the **dont_touch** value on the cells or nets, use the **report_cell** or **report_net** command. The **dont_touch** assignment stops at registers. An element is recognized as a register only if it has setup or hold constraints. If you specify a clock, the transitive fanout of all the clock's sources is affected. The **report_net** command displays the nets that are implicitly **dont_touch** as a result of using the **set_dont_touch_network** command.

The **set_dont_touch_network** command is intended primarily for clock circuitry. Placing a **dont_touch_network** on a clock object prevents the **compile** command from modifying the clock buffer network.

Note that the **dont_touch_network** attribute does not prevent compile from mapping unmapped logic (for example, cells read in from an HDL description).

To remove the **dont_touch_network** attribute, use the **remove_attribute** command on specific object on which **dont_touch_network** has been set.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command adds a **dont_touch_network** attribute to a port named *clock_in*:

```
prompt> set_dont_touch_network clock_in
```

The following command removes the **dont_touch_network** attribute on port named *clock_in*:

```
prompt> remove_attribute [get_port clock_in] dont_touch_network
```

SEE ALSO

```
remove_attribute(2)
report_cell(2)
report_clock(2)
report_design(2)
report_net(2)
report_port(2)
set_dont_touch(2)
```

set_dont_touch_placement

Fixes the location of a cell or cluster.

SYNTAX

```
status set_dont_touch_placement  
object_list
```

ARGUMENTS

`object_list`
List of objects, each of which is a leaf cell or cluster.

DESCRIPTION

This command fixes the location of a leaf cell or cluster by applying fixed placement restriction. The placement of these cells will not be altered.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to prevent the placer from moving the instance INST_1.

```
prompt> set_dont_touch_placement INST_1
```

SEE ALSO

```
set_cell_location(2)  
create_placement(2)  
remove_dont_touch_placement(2)
```

set_dont_use

Sets the **dont_use** attribute on library cells to exclude them from the target library during optimization.

SYNTAX

```
int set_dont_use  
[-power] object_list
```

Data Types

object_list list

ARGUMENTS

-power

Specifies that the list of objects passed should not be considered for Power Compiler clock gate mapping in addition to excluding them from target library. Without this switch the objects are excluded from target library, but are still available to Power Compiler for clock gate mapping.

object_list

Specifies a list of objects (*lib_cells*, *modules*, or *implementations*) on which the **dont_use** attribute is to be set. Object names must contain a library prefix; for more information, refer to the EXAMPLES section of this manual page, and to the manual page for the **find** command. If more than one objects is included, they must be enclosed in quotes or braces ({}).

DESCRIPTION

Sets the **dont_use** attribute on specified library objects, so that they are not used. The specified objects must be in one of the target libraries or in a library already loaded into Design Analyzer. If this attribute exists on a library cell, module or implementation **compile** does not use it for a design.

When -power switch is used, an additional attribute *pwr_cg_don_use* is set in addition to *dont_use*. When this attribute is present on an object, Power Compiler will not consider it for mapping.

NOTE: This command affects only the copy of the library that is currently loaded into memory, and has no effect on the version that exists on disk. However, if the library is written out using **write_lib**, any **dont_use** attribute will be written out, causing library objects to be permanently disabled.

To remove **dont_use** attributes, use the **remove_attribute** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command disables the lib_cells called 'G1' and 'G2' from the 'tech_lib' library:

```
prompt> set_dont_use {tech_lib/G1 tech_lib/G2}
```

The following command disables the implementations called 'imp1' and 'imp2' from the module 'syn_lib/mod':

```
prompt> set_dont_use {syn_lib/mod/imp1 syn_lib/mod/imp2}
```

The following command removes the lib_cells called 'icg_1' icg_2' from the list of integrated clock gating lib_cells available for clock gate mapping.

```
prompt> set_dont_use -power {tech_lib/icg_1 tech_lib/icg_2}
```

SEE ALSO

`remove_attribute(2)`
`report_lib(2)`
`target_library(3)`

set_dp_int_round

Set the rounding positions on datapath output nets.

SYNTAX

```
status set_dp_int_round
nets
external_rounding_position
[internal_rounding_position]
```

Data Types

<i>nets</i>	list
<i>external_rounding_position</i>	int
<i>internal_rounding_position</i>	int

ARGUMENTS

<i>nets</i>	List of nets that the rounding will be applied to.
<i>external_rounding_position</i>	The bit position for external rounding.
<i>internal_rounding_position</i>	The bit position for internal rounding.

DESCRIPTION

This command specifies the external and internal rounding positions on the supported nets that are driven by a DW multiplier-like component or a DW complex datapath block.

The supported nets are: Nets that are driven by cells that infer DesignWare operator MULT_UNS_OP and MULT_TC_OP; Nets that are driven by cells that instantiate the following DesignWare components: DW02_mult, DW_mult_uns, DW_mult_tc, DW_square, DW02_prod_sum, DW02_prod_sum1, DW_prod_sum_uns, DW_prod_sum_tc, DW02_mac, DW_mac_tc, DW_mac_uns.

Internal rounding allows to make a tradeoff between precision and area in arithmetic circuits. All bits lower than the internal rounding position are discarded from the internal addends. Area is saved because no logic is required to generate and add these bits. However, a rounding error is introduced, which degrades the precision of the result. An offset is automatically added to keep the error range as symmetric and the bias as small as possible.

The result of a datapath with internal rounding is usually truncated somewhere above the internal rounding position. This truncation can also be rounded by setting the external rounding position to this bit position. Rounding is achieved by adding a constant 1 at the next lower bit position.

Since internal rounding changes the functionality of a datapath block, a behavioral model that reflects the changed functionality is written out as Verilog file. This behavioral Verilog file can be used for simulation and verification of the new netlist. The file is created in the `dwsfv` directory.

A rounding error report is printed with the `report_resources` command.

To remove the rounding attribute, use the `remove_dp_int_round` command.

A few notes about using this command: 1. Currently, if you set_implementation on the cells that infer DesignWare operators, internal rounding will not happen. 2. We only support internal rounding on generated implementations. Therefore, if you set_implementation to the non-generated implementation for a instantiated DesignWare cell, the internal rounding will not happen.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the external rounding position on net `z1*` to be 7, and the internal rounding position to be 5:

```
prompt> set_dp_int_round [get_nets z1*] 7 5
```

The `report_resources` command reports the rounding errors:

```
prompt> report_resources
```

DW rounding error report in design `mult_inst_DW_mult_uns_1`(cell `mult_6`):
Rounding Error Report for product[15:0]

Rounding	to Bit	Relative Error			Absolute Error		
		Min	Max	Avg	Min	Max	Avg
Internal	5	-3.00	2.00	-0.50	-96	64	-16
<hr/>							
Internal	7	-0.75	0.50	-0.12	-96	64	-16
External	7	-0.50	0.49	-0.00	-64	63	-0.5
Total	7	-1.25	0.99	-0.13	-160	127	-16.5
<hr/>							

The behavioral Verilog file has extension `.bvrl` and is found in the `dwsfv_*` directory:

```
prompt> ls dwsfv_*
dwarchs-0.v.e  mult_inst_DW_mult_uns_1.round.bvrl
```

SEE ALSO

`remove_dp_int_round(2)`

`set_dp_int_round`
2244

set_drive

Sets the **rise_drive** or **fall_drive** attributes to specified resistance values on specified input and inout ports.

SYNTAX

```
int set_drive
  resistance
  [-rise] [-fall] [-min] [-max]
  port_list
```

Data Types

<i>resistance</i>	float
<i>port_list</i>	list

ARGUMENTS

resistance

Specifies a nonnegative resistance value to which the **rise_drive** or **fall_drive** attributes are to be set on the ports in *port_list*. The *resistance* is the output resistance of the cell that drives the port, such that a higher drive strength (resistance) means less drive capability and longer delays. Thus, a *resistance* of 0 is infinite drive, or no delay between the ports and all that is connected to them. The *resistance* must be in unit consistent with the technology library used during optimization.

-rise -fall

Indicates that the **rise_drive** or **fall_drive** attributes of *port_list* are to be set to *resistance*. If you don't specify either, both are set to *resistance*.

-min -max

Indicates that the drive strength is to be applied for minimum or maximum delay analysis. If no value is specified for minimum analysis, the maximum value is used.

port_list

Specifies a list of input or inout port names of the current design on which the drive attributes are to be set. If you specify more than one port, you must enclose the ports in either quotes or braces ({}).

DESCRIPTION

Sets the **rise_drive** or **fall_drive** attributes to *resistance* on specified input and inout ports in the current design.

Note: The **set_driving_cell** command is more convenient and accurate than **set_drive** for describing the drive capability of a port. The **set_drive** command removes any corresponding rise or fall driving cell attributes on the specified ports. Use **set_driving_cell** instead of **set_drive**, if possible.

During optimization, the drive of an input port is used to calculate the timing delay to gates driven by that port. The delay to these gates is computed as follows for the generic CMOS delay model:

```
Time = arrival_time + [drive * load(net)] + connect_delay (if any)
```

To view drive information on ports, use **report_port -drive**. To remove drive attributes from ports, use **remove_attribute**. The **reset_design** command removes all attributes from a design, including the drive attributes.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets the rise and fall drives of ports "A", "B", and "C" to 2.0.

```
prompt> set_drive 2.0 {A B C}
```

The following example sets the rise and fall drives of all input ports to 2 and sets the rise drive on port "B" to 1.

```
prompt> set_drive 2 all_inputs( )
prompt> set_drive -rise 1 B
```

The following example sets both rise and fall drives of port "C" to corresponding drives of pin "OUT" of "INVERTER" from "TECH_LIBRARY" using the **drive_of** command.

```
prompt> set_drive -rise drive_of(-rise TECH_LIBRARY/INVERTER/OUT) {C}
prompt> set_drive -fall drive_of(-fall TECH_LIBRARY/INVERTER/OUT) {C}
```

set_driving_cell

Sets attributes on input or inout ports of the current design, specifying that a library cell or pin drives ports.

SYNTAX

```
int set_driving_cell
[-lib_cell lib_cell_name]
[-library lib]
[-rise]
[-fall]
[-min]
[-max]
[-pin pin_name]
[-from_pin from_pin_name]
[-dont_scale]
[-no_design_rule]
[-none]
[-input_transition_rise rtran]
[-input_transition_fall ftran]
[-multiply_by factor]
port_list
[-cell obsolete_-_please_use_-lib_cell_instead]
```

Data Types

<i>lib_cell_name</i>	string
<i>lib</i>	string
<i>pin_name</i>	string
<i>from_pin_name</i>	string
<i>rtran</i>	float
<i>ftran</i>	float
<i>factor</i>	float
<i>port_list</i>	list

ARGUMENTS

-lib_cell *lib_cell_name*

Specifies the name of the library cell to use to drive ports. You can use this option with the **-pin** option when the cell has more than one output pin to set the **driving_cell_rise** and the **driving_cell_fall** string attributes to *lib_cell_name* on the ports. To specify different cells for the rising and falling cases, execute the command twice, once using the **-rise** option and once using the **-fall** option, specifying the appropriate *lib_cell_name* for each. When you use this option, you must also use the **-dont_scale** and **-multiply_by** options. By default, the command searches the libraries in **link_library** for the cell.

-library *lib*

Specifies the library name or a collection of libraries in which to find the name of the library cell to use to drive ports (*lib_cell_name*). If the lib cell can be found in multiple libraries, the library with matching operating

condition on the port will be used. When no library is specified, all the libraries will be searched for the lib cell with matching operating condition. If the one with matching operating condition is not found, the first one with matching lib cell name will be used.

You can use this option only with the **-lib_cell** option to set the **driving_cell_library_rise** and the **driving_cell_library_fall** string attributes to the library name on the ports. To specify different libraries for the rising and falling cases, execute the command twice, using the **-rise** option and once using the **-fall** option, specifying the appropriate lib for each.

-rise

Specifies that the *lib_cell_name*, *lib*, *pin_name*, and *from_pin_name* correspond to the rising case, and sets the **driving_cell_rise**, **driving_cell_library_rise**, **driving_cell_pin_rise**, and **driving_cell_from_pin_rise** attribute strings, respectively, on the objects. You can use this option with the **-fall** option to specify both the rising and the falling case.

-fall

Specifies that the *lib_cell_name*, *lib*, *pin_name*, and *from_pin_name* correspond to the falling case, and sets the **driving_cell_fall**, **driving_cell_library_fall**, **driving_cell_pin_fall**, and **driving_cell_from_pin_fall** attribute strings, respectively, on the objects. You can use this option with **-rise** to specify both the rising and the falling case.

-min

Sets driving_cell information for only the minimum analysis.

-max

Sets driving_cell information for only the maximum analysis.

-pin *pin_name*

Specifies the output pin on the driving cell that is to drive the ports. The **-pin** option is required when you use the **-lib_cell** option and the driving cell has more than one output pin or when using the **-from_pin** option. This option sets the **driving_cell_pin_rise** and the **driving_cell_pin_fall** string attributes to *pin_name* on the ports. To specify different pins for the rising and falling cases, execute the command twice, once using the **-rise** option and once using the **-fall** option, specifying the appropriate *pin_name* for each. The default is to use the first timing arc found on the library cell.

-from_pin *from_pin_name*

Specifies the input pin on the driving cell to use when finding a timing arc. This option is required when the driving cell has more than one input pin and the arcs from those pins have different drive characteristics, and when using the **-pin** and **-lib_cell** options. The **-from_pin** option sets the **driving_cell_from_pin_rise** and **driving_cell_from_pin_fall** string attributes to *from_pin_name* on the ports. The default is to use the first timing arc found on the library cell.

-dont_scale

Specifies that the timing analyzer is not to scale the drive capability of the ports according to the current operating conditions. You must use this

option when using the **-lib_cell** option. The **-dont_scale** option sets the **driving_cell_dont_scale** Boolean attribute to **true** on the ports. By default, the port drive capability is scaled for operating conditions exactly as the driving cell would be scaled.

-no_design_rule

Indicates that the design rules associated with the driving cell are not to be applied to the driven port. This option sets the **driving_cell_no_drc** Boolean attribute to **true** on the ports. Timing-related attributes are still applied. The tool issues a warning if this option is not used. By default, design rule attributes (**max_fanout**, **max_capacitance**, **max_transition**, **min_fanout**, **min_capacitance**, **min_transition**) are derived from the driving cell and its library and applied to the port.

-none

Removes previous driving_cell info.

-input_transition_rise rtran

Specifies the input rise transition time associated with the **-from_pin** option. Use the **-input_transition_rise** and **-input_transition_fall** options to obtain a more accurate transition time and delay time at the output pin by capturing the accurate transition time associated with the **-from_pin**. The default value is **0**.

-input_transition_fall ftran

Specifies the input fall transition time associated with the **-from_pin** option. The default value is **0**.

-multiply_by factor

Specifies a factor by which to multiply the delay characteristics of the ports. You must use this option when using the **-lib_cell** option. It affects both the load delay and the transition times of the port. It sets the **driving_cell_multiply_by** float attribute to *factor* on the ports. The default is **1.0**.

port_list

Specifies a list of names of input or inout ports in the current design on which the driving cell attributes are to be placed. If more than one port is specified, they must be enclosed in either quotes or braces ({}).

DESCRIPTION

This command sets attributes on the specified input or inout ports in the current design to associate an external driving cell with the ports. The drive capability of the port is the same as if the specified driving cell were connected in the same context to allow accurate modeling of the port drive capability for nonlinear delay models. For the CMOS2 delay model, the edge rate of pins driven by the port is the same as if the driving cell were substituted for the port. Unless you specify the **-dont_scale** option, the drive capability of the port is scaled according to the current operating conditions.

To view drive information on ports, use the **report_port** command with the **-drive** option.

You can use the **characterize** command to automatically set driving cell attributes on subdesign ports based on their context in the entire design.

You can use the **remove_driving_cell** or **reset_design** command to remove driving cell attributes on ports. The **remove_driving_cell** command removes any corresponding rise or fall drive resistance attributes (from the **set_drive** command) on the specified ports. It is considered best practice to use the **set_driving_cell** command instead of **set_drive**, because **set_driving_cell** is more accurate.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example associates the drive capability of the *AND2* library cell with the *IN1* port.

```
prompt> set_driving_cell -lib_cell AND2 {IN1}
```

The following example associates the drive capability of the *INV/Z* library pin from the *tech_lib* library with all input and inout ports.

```
prompt> set_driving_cell -lib_cell INV -pin Z \
-library tech_lib all_inputs()
```

The following example associates the drive capability of the *INV* library cell with the *IN1* port and specifies that the delay values should not be scaled by operating conditions factors.

```
prompt> set_driving_cell -lib_cell INV -dont_scale {IN1}
```

The following example associates the *Z* pin of *BUF1_TS* with the *IN1* port for rising delays and the *Q* pin of *DFF_TS* for falling delays.

```
prompt> set_driving_cell -rise -lib_cell BUF1_TS -pin Z
prompt> set_driving_cell -fall -lib_cell DFF_TS -pin Q {IN1}
```

The following example sets the *AN2* driving cell to the *top1* input port with an input rise transition time of 2.3 on *A* specified by the **-from_pin** option.

```
prompt> set_driving_cell -lib_cell AN2 \
-input_transition_rise 2.3 -from_pin A top1
```

set_droute_options

Sets detailed router cell-persistent options.

SYNTAX

```
status set_droute_options
[-name ]
[-value ]
[-default]
```

ARGUMENTS

-name name
Specifies the name of the option to be set. Use command **report_droute_options** to check for valid names.

-value value
Specifies the value of the option to be set. Use command **report_droute_options -name** to check for valid range, type, default value, current value and a brief description of a named option.

-default
Set all droute options to their default values. To set a specific droute option to its default value, use "-name" and "-value" arguments. Use command **report_droute_options** to check for default value.

DESCRIPTION

The **set_droute_options** command sets options to tune detailed router operation. These settings are persistent in the Milkyway design. This command saves cell-persistent options in cell data base, and marks cell as being modified. To permanently save these options, you have to save cell upon exit. This command is optional, if you want defaults to apply. All options are optional too. However, if you want to set a specific option value, "-name" and "-value" have to be specified. To reset all options to their default values, use "-default" argument. To print all available detailed router options, their current value, default value, range, type and a brief description, use command **report_droute_options**

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> set_droute_options -name shiftVarWidthWire -value 2
prompt> set_droute_options -name via1MacroDensity -value 20.0
prompt> set_droute_options -default
```

SEE ALSO

`report_droute_options(2)`

set_equal

Defines two input ports as logically equivalent.

SYNTAX

```
int set_equal
port1
port2
```

Data Types

```
port1      string
port2      string
```

ARGUMENTS

```
port1 port2
Two logically-equivalent input port in the current design.
```

DESCRIPTION

Defines two input ports in the current design as logically equivalent. This information is used to eliminate redundant ports, improving optimization quality.

Logical inconsistencies are checked for in relationships between ports. Specifying an inconsistent logical relationship between ports is not allowed.

Use the **reset_design** command to remove this property from a port.

EXAMPLES

The following example sets two input ports "A" and "B" logically equal:

```
prompt> set_equal A B
```

The following example sets up a contradictory relationship between two ports and creates an error:

```
prompt> set_equal A B
prompt> set_opposite A B
Warning: Can't set equal ports opposite in design 'example.ddc': 'A' 'B'
```

SEE ALSO

```
reset_design(2)
set_opposite(2)
current_design(3)
```

set_error_view_property

Write error view properties. Fails with a warning if a property already exists.

SYNTAX

```
status set_error_view_property
[-error_view mw_error_view]
[-writer product_name]
[-version version_string]
[-ignore_type_name_property true | false]
[-run_set run_set_name]
[-areas areas]
[-excluded_areas areas]
[-command command_string]
```

Data Types

<i>mw_error_view</i>	list or collection
<i>product_name</i>	string
<i>version_string</i>	string
<i>run_set_name</i>	string
<i>areas</i>	string
<i>command_string</i>	string

ARGUMENTS

-error_view *mw_error_view*

The error view to which to add or replace the property values. If omitted, the properties are written to the current top-level design cell. Specifying more than one error view causes an error.

-writer *product_name*

Write the "Writer" property. This is the product name of the error view writer.

-version *version_string*

Write the "Version" property. This is the product version of the error view writer.

-ignore_type_name_property true | false

Write the "IgnoreTypeNameProperty" property. If this property is true, then the TypeName property of error type is ignored. This TypeName property is used to store type names that are longer than can be stored in the regular schema. If value is false, "IgnoreTypeNameProperty" property may be deleted.

-run_set *run_set_name*

Write the "Runset" property. This is the name of the runset file input to the DRC check.

-areas *areas*

Write the "Areas" property. These are the areas of the design that were included in the DRC check.

```
-excluded_areas areas
    Write the "ExcludedAreas" property. These are the areas of the design that
    were excluded from the DRC check.

-command command_string
    Write the "Command" property. This is the command string which invoked the
    DRC or LVS check which produced the error view.
```

DESCRIPTION

This command writes error view properties which help with interpretation of the error data. Error view properties are also a way to record how the error objects in the error view were created. The options allow writing a subset of the available properties which are the ones that are likely to be written by a client writing to an error view using the Tcl API. If a property already exists, the command will fail. If the error view schema version property is not yet written, this command will automatically write the current schema version.

SEE ALSO

[get_error_view_property\(2\)](#)

set_extraction_options

Sets the parameters that influence extraction.

SYNTAX

```
status set_extraction_options
[-max_cap_scale max_cap_scaling]
[-min_cap_scale min_cap_scaling]
[-max_res_scale max_res_scaling]
[-min_res_scale min_res_scaling]
[-max_ccap_scale max_ccap_scaling]
[-min_ccap_scale min_ccap_scaling]
[-max_net_ccap_thres max_net_ccap_threshold]
[-min_net_ccap_thres min_net_ccap_threshold]
[-max_net_ccap_ratio max_net_ccap_ratio]
[-min_net_ccap_ratio min_net_ccap_ratio]
[-max_net_ccap_avg_ratio max_net_ccap_avg_ratio]
[-min_net_ccap_avg_ratio min_net_ccap_avg_ratio]
[-max_process_scale max_process_scaling]
[-min_process_scale min_process_scaling]
[-no_obstruction]
[-no_break_segments]
[-max_segment_length max_segment_length]
[-real_metalfill_extraction none | floating | grounded | auto]
[-virtual_shield_extraction true | false]
[-fan_out_thres high_fan_out_threshold]
[-default]
```

Data Types

<i>max_cap_scaling</i>	float
<i>min_cap_scaling</i>	float
<i>max_res_scaling</i>	float
<i>min_res_scaling</i>	float
<i>max_ccap_scaling</i>	float
<i>min_ccap_scaling</i>	float
<i>max_net_ccap_threshold</i>	float
<i>min_net_ccap_threshold</i>	float
<i>max_net_ccap_ratio</i>	float
<i>min_net_ccap_ratio</i>	float
<i>max_net_ccap_avg_ratio</i>	float
<i>min_net_ccap_avg_ratio</i>	float
<i>max_process_scaling</i>	float
<i>min_process_scaling</i>	float
<i>max_segment_length</i>	integer
<i>high_fan_out_threshold</i>	integer

ARGUMENTS

-max_cap_scale *max_cap_scaling*

Specifies the factor to be multiplied by the maximum capacitance. The default value is 1.0.

-min_cap_scale *min_cap_scaling*
Specifies the factor to be multiplied by the minimum capacitance. The default value is 1.0.

-max_res_scale *max_res_scaling*
Specifies the factor to be multiplied by the maximum resistance. The default value is 1.0.

-min_res_scale *min_res_scaling*
Specifies the factor to be multiplied by the minimum resistance. The default value is 1.0.

-max_ccap_scale *max_ccap_scaling*
Specifies the factor to be multiplied by the maximum coupling capacitance. The default value is 1.0.

-min_ccap_scale *min_ccap_scaling*
Specifies the factor to be multiplied by the minimum coupling capacitance. The default value is 1.0.

-max_net_ccap_thres *max_net_ccap_threshold*
Specifies the net-to-net filtering threshold for the maximum coupling capacitance. The unit is your main library unit. The default value is 0.003 pF.

-min_net_ccap_thres *min_net_ccap_threshold*
Specifies the net-to-net filtering threshold for the minimum coupling capacitance. The unit is your main library unit. The default value is 0.003 pF.

-max_net_ccap_ratio *max_net_ccap_ratio*
Specifies the net-to-net filtering ratio for the maximum coupling capacitance. The default value is 0.03 of the total capacitance.

-min_net_ccap_ratio *min_net_ccap_ratio*
Specifies the net-to-net filtering ratio for the minimum coupling capacitance. The default value is 0.03 of the total capacitance.

-max_net_ccap_avg_ratio *max_net_ccap_avg_ratio*
Specifies the net-to-net filtering ratio based on average net-to-net ccap for the maximum coupling capacitance. This ratio can be bigger than 100% of average coupling capacitance. The default value is 0, which means it is off.

-max_process_scale *max_process_scaling*
Specifies the maximum process scaling factor. The default value is 1.0.

-min_process_scale *min_process_scaling*
Specifies the minimum process scaling factor. The default value is 1.0.

-no_obstruction
Ignores routing obstructions during extraction.

-no_break_segments
Specifies that long wire segments are not broken during extraction.

-max_segment_length *max_segment_length*

Specifies the maximum length of wire segment. This option has no effect if the **-no_break_segments** option is used. The default value is 50um.

-real_metalfill_extraction *none* | *floating* | *grounded* | *auto*

This option applies to post route extraction only. It specifies the metal fill extraction mode. The default value is **none**. Use this option in conjunction with the **set_tlu_plus_files** command. The valid values have different meaning depending on **set_tlu_plus_files**.

If you specify emulation TLUPlus files in **set_tlu_plus_filess** using **-max_emulation_tluplus** and/or **-min_emulation_tluplus**, and set **-real_metalfill_extraction** to **none**, the tool performs metal fill emulation extraction as follows:

- Does not read in metal fill polygons from the MilkyWay database.
- Uses emulation TLUplus files in the extraction process.

If you set the value to **floating**, **grounded**, or **auto**, the tool performs real metal fill extraction as follows:

- Reads in metal fill polygons for processing.
- Uses normal *tluplus* files specified with **-max_tluplus** and/or **-min_tluplus** in the extraction.

If only **-max_tluplus** or **-min_tluplus** are specified in the **set_tlu_plus_file** (without **-max_emulation_tluplus** and **-min_emulation_tluplus**), and you set **-real_metalfill_extraction** to **none**, the tool performs normal extraction, without reading in the fill polygons.

There are different models when handling metal fill polygons in real metal fill extraction, based on the option value you selected:

none - The tool performs either normal extraction or emulation metal fill extraction, depending on the settings used in the **set_tlu_plus_files** command.

floating - The tool reads in metal fill polygons for processing use normal TLUPlus files specified using **-max_tluplus** and/or **-min_tluplus** in the extraction. The metal fill polygons are as treated as floating and the tool reduces the coupling capacitance to the fill polygon to the next signal net.

grounded - The metal fill polygons as treated as grounded and uses grounding coupling capacitance to fill polygons to VDD/VSS.

auto - The metal fill polygons are treated as is, based on the fill wire track property and net ID.

-virtual_shield_extraction *true* | *false*

This option applies to post route extraction only. When this option is set to **true** (default value), ICC performs virtual shield extraction by considering shielding rules. Otherwise, shileding rules are not considered during extraction. Shielding rules are defined in Nondefault Routing rules (NDRs) using the **define_routing_rule** command. Both the nets with NDR defined and their neighbors may see their RC affected due to shielding effects when this option is set to **true**.

Note that as of version Y-2006.06-SP2, this option replaces the **physopt_enable_virtual_shield** variable.

-fan_out_thres *high_fan_out_threshold*

Specifies the high fanout threshold for extraction so that nets with a higher fanout than the threshold are not extracted. The default value is 1000.

```
-default
    Resets all options to their default values.
```

DESCRIPTION

The **set_extraction_options** command specifies the parameters that influence the extraction engine.

The following options specify the scaling factors for capacitance, resistance, and coupling capacitance:

```
[-max_cap_scale max_cap_scaling]
[-min_cap_scale min_cap_scaling]
[-max_res_scale max_res_scaling]
[-min_res_scale min_res_scaling]
[-max_ccap_scale max_ccap_scaling]
[-min_ccap_scale min_ccap_scaling]
```

This set of scaling factors is treated separately from the scaling factors specified with the **set_delay_estimation_options** command, which controls preroute resistance and capacitance estimation.

The following options control the coupling capacitance filtering:

```
[-max_net_ccap_thres max_net_ccap_threshold]
[-min_net_ccap_thres min_net_ccap_threshold]
[-max_net_ccap_ratio max_net_ccap_ratio]
[-min_net_ccap_ratio min_net_ccap_ratio]
[-max_net_ccap_avg_ratio max_net_ccap_avg_ratio]
[-min_net_ccap_avg_ratio min_net_ccap_avg_ratio]
```

The unit used as the threshold is your main library unit. If your main library unit is in picofarad, and you want to specify 0.2 fF as the threshold, set the value to 0.0002. If your main library unit is in femtofarad, set the value to 0.2. The ratio controls the relativity of the filtering, and the default value is 0.03 of the total capacitance.

You can also specify process scaling factors with the **-max_process_scale** and **-min_process_scale** options. Process scaling factors can impact both **extract_rc** and **extract_rc -estimate** command activity if **extract_rc -estimate** uses extractor or TLUPplus-based RC.

Use this command with the **set_tlu_plus_files** command.

LIMITATIONS

The command is only available in DC-Topographical mode.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example runs the **set_extraction_options** command with a 1.20 - **max_cap_scale** factor and a 0.7 **-min_cap_scale** factor:

```
prompt> set_extraction_options -max_cap_scale 1.20 -min_cap_scale 0.7
```

SEE ALSO

`define_routing_rule(2)`

set_false_path

Removes timing constraints from particular paths.

SYNTAX

```
int set_false_path
[-rise | -fall] [-setup | -hold]
[-from from_list
 | -rise_from rise_from_list
 | -fall_from fall_from_list]
[-through through_list]
[-rise_through rise_through_list]
[-fall_through fall_through_list]
[-to to_list
 | -rise_to rise_to_list
 | -fall_to fall_to_list]
[-reset_path]
```

Data Types

<i>from_list</i>	list
<i>rise_from_list</i>	list
<i>fall_from_list</i>	list
<i>through_list</i>	list
<i>rise_through_list</i>	list
<i>fall_through_list</i>	list
<i>to_list</i>	list
<i>rise_to_list</i>	list
<i>fall_to_list</i>	list

ARGUMENTS

-rise

Marks rising delays false, as measured on the path endpoint. If you do not specify either **-rise** or **-fall**, both rise and fall timing are marked false.

-fall

Marks falling delays false, as measured on the path endpoint. If you do not specify either **-rise** or **-fall**, both rise and fall timing are marked false.

-setup

Marks setup (maximum) paths false. **-setup** disables setup checking for specified paths. If you do not specify either **-setup** or **-hold**, both setup and hold timing are marked false.

-hold

Marks hold (minimum) paths false. **-hold** disables hold checking for specified paths. If you do not specify either **-setup** or **-hold**, both setup and hold timing are marked false.

-from *from_list*

Specifies start points (clocks, ports, pins, or cells) of disabled paths. If

you do not specify a *from_list*, all paths to end points in *to_list* are disabled. *from_list* can include clocks, pins, or ports. If you specify a clock, all path startpoints related to the specified clock are affected. If you specify an internal pin, the pin must be a path startpoint (the clock pin of a flip-flop, for example). If a cell is specified, one path startpoint on that cell is affected.

-rise_from *rise_from_list*

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Same as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through *through_list*

A list of path throughpoints (port, pin, or leaf cell names) of the current design. The false path applies only to paths that pass through one of the points in the *through_list*. If more than one object is included, you must enclose the objects in quotes or in '{}' braces. If you specify the **-through** option multiple times, the false path setting applies to paths that pass through a member of each *through_list* in the order the lists were given. That is, the path must first pass through a member of the first *through_list*, then through a member of the second list, and so on for every through list specified. If you use the **-through** option in combination with the **-from** or **-to** options, the false path applies only if the **-from** or **-to** conditions are satisfied and the **-through** conditions are satisfied.

-rise_through *rise_through_list*

Same as the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than once in a single command invocation as with the **-through** option.

-fall_through *fall_through_list*

Same as the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than once in a single command invocation as with the **-through** option.

-to *to_list*

Specifies end points (clocks, ports, pins, or cells) of paths disabled. If you do not specify *to_list*, all paths from start points in *from_list* are disabled. The *to_list* can include clocks, pins, or ports. If you specify a clock, all path endpoints related to the specified clock are considered. If you specify an internal pin, the pin must be a path endpoint (for example, the data pin of a flip-flop). If you specify a cell, one path endpoint on that cell is affected.

```

-rise_to rise_to_list
    Same as the -to option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of -to, -rise_to, and -fall_to.
```

```

-fall_to fall_to_list
    Same as the -to option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of -to, -rise_to, and -fall_to.
```

```

-reset_path
    Removes existing point-to-point exception information on the specified paths. Only information of the same rise/fall or setup/hold type is reset. This is equivalent to using the reset_path command with similar arguments before the set_false_path is issued.
```

DESCRIPTION

Removes timing constraints from specified paths that you know do not affect circuit operation. **set_false_path** can disable both maximum delay (setup) checking and minimum delay (hold) checking.

The **set_false_path** command disables timing from path startpoints through path throughpoints to path endpoints. Path startpoints are input ports or register clock pins. Path throughpoints can be cells, pins, or ports. Path endpoints are register data pins or output ports.

To disable the timing at a particular cell in the design, use **set_disable_timing**. This removes certain timing arcs on a cell from the timing graph, so that paths along those arcs are not traced. The **set_false_path** command still allows tracing of the paths, but removes any timing constraints on them.

set_false_path is a point-to-point timing exception command. This means it assists in overriding the default single-cycle timing relationship for one or more timing paths. Other point-to-point timing exception commands include **set_max_delay**, **set_min_delay**, and **set_multicycle_path**.

If a path satisfies multiple timing exceptions, the following rules assist in determining which exceptions take effect. Rules referring to **-from** apply equally to **-rise_from** and **-fall_from**, and similarly for the rise and fall options of **-through** and **-to**.

1. Two **group_path** commands might conflict with each other. But a **group_path** exception by itself does not conflict with another type of exception. So the remaining rules apply for two **group_path** exceptions, or two non-**group_path** exceptions.

2. If both exceptions are **set_false_paths**, there is no conflict.

3. If one exception is a **set_max_delay** and the other is **set_min_delay**, there is no conflict.

4. If one exception is a **set_multicycle_path -hold** and the other is **set_multicycle_path -setup**, there is no conflict.

5. If one exception is a **set_false_path** and the other is not, the **set_false_path** takes precedence.

6. If one exception is a **set_max_delay** and the other is not, the **set_max_delay** takes precedence.

7. If one exception is a **set_min_delay** and the other is not, the **set_min_delay** takes precedence.

8. If one exception has a **-from pin** or **-from cell** and the other does not, the former takes precedence.

9. If one exception has a **-to pin** or **-to cell** and the other does not, the former takes precedence.

10. If one exception has any **-through** points and the other does not, the former takes precedence.

11. If one exception has a **-from** clock and the other does not, the former takes precedence.

12. If one exception has a **-to** clock and the other does not, the former takes precedence.

13. The exception with the more restrictive constraint then takes precedence. For **set_max_delay** and **set_multicycle_path -setup**, this is the constraint with the lower value. For **set_min_delay** and **set_multicycle_path -hold**, it is the constraint with the higher value.

To undo the effect of **set_false_path**, use **reset_path** or **reset_design**.

Use **report_timing_requirements** to list the point-to-point exceptions on a design.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes timing constraints on paths from "ff12" to "ff34".

```
prompt> set_false_path -from {ff12} -to {ff34}
```

The following example removes timing constraints on paths through "u14/Z" to "ff29/Reset" which are rising at the endpoint.

```
prompt> set_false_path -rise -through {u14/Z} -to {ff29/Reset}
```

The following example disables hold checking (minimum delay timing) for endpoints clocked by "PHI1". The flip-flops and latches clocked by "PHI1" are checked for setup violations, but not for hold violations.

```
prompt> set_false_path -hold -to [get_clocks PHI1]
```

The following example removes timing constraints for all paths that first pass through either "u1/Z" or "u2/Z" then pass through "u5/Z" or "u6/Z".

```
prompt> set_false_path -through {u1/Z u2/Z} -through {u5/Z u6/Z}
```

The following example disables rising timing paths through "U14/Z" to "ff29/Reset".

```
prompt> set_false_path -rise_through {U14/Z} -to {ff29/Reset}
```

SEE ALSO

current_design(2)

set_max_delay(2)
set_min_delay(2)
set_multicycle_path(2)

set_fanout_load

Sets the **fanout_load** attribute to a specified value on specified output ports of the current design.

SYNTAX

```
int set_fanout_load  
value  
port_list
```

Data Types

value	float
port_list	list

ARGUMENTS

value

Specifies the value to which the **fanout_load** attribute is to be set on the ports in *port_list*. *value* must be expressed in units consistent with the **max_fanout** and **fanout_load** values in the technology library used during optimization.

port_list

Specifies the ports in the current design on which the **fanout_load** attribute is to be set. If more than one port is specified, they must be enclosed either in quotes or in braces ({}).

DESCRIPTION

Sets the **fanout_load** attribute to a specified value on specified output ports in the current design. **compile** attempts to ensure that the sum of this value, together with all **fanout_load** attributes for pins connected to the driver that drives this port, does not exceed the driving pin's **max_fanout** capability. The default **fanout_load** value for a port is 0.0.

NOTE: Bidirectional ports are not included in maximum fanout calculations, so using the **set_fanout_load** command with a bidirectional port has no effect on **compile**.

Use **remove_attribute** or **reset_design** to remove **fanout_load** values from ports. Use **report_port** to list fanout load values on ports.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command sets a fanout load of 2 units on all output ports:

```
set_fanout_load  
2268
```

```
prompt> set_fanout_load 2 all_outputs()
```

SEE ALSO

`all_outputs(2)`
`remove_attribute(2)`
`report_port(2)`
`reset_design(2)`
`set_max_fanout(2)`

set_fast_mode

Turns on or turns off fast mode.

SYNTAX

```
status set_fast_mode
[-no_congestion]
[set_fast_mode]
```

ARGUMENTS

-no_congestion

Prevents the place_opt stage of the fast mode from performing congestion removal at the end.

set_fast_mode

Turns fast mode on or off. Valid values are **true** or **false**.

DESCRIPTION

This command takes a boolean value: when it is true, the fast mode is turned on; when it is false, the fast mode is turned off. If the boolean value is not given, by default it turns on the fast mode. Option specified by **set_fast_mode** take precedence over the mega commands. In other words, the command **set_fast_mode** changes the flow effort setting in the mega commands. But it does not affect any atomic commands. By default, the fast mode has congestion removal at the end of place_opt stage. To disable it, specify **-no_congestion** option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example turns on the fast mode without congestion removal in place_opt stage.

```
prompt> set_fast_mode true -no_congestion
Info: turn on fast mode
```

SEE ALSO

`report_fast_mode(2)`

set_feasibility_options

Sets feasibility options for place_opt and reporting commands.

SYNTAX

```
status set_feasibility_options
[-enable true | false]
[-zero_path_violations true | false]
[-zero_wire_load_violations true | false]
[-zero_path_margin zero_path_margin_num]
[-zero_wire_load_margin zero_wire_load_margin_num]
[-io_margin io_margin_num]
[-group_io true | false]
[-design_slack_threshold slack_threshold_num]
[-slack_threshold_path_groups path_groups_list]
[-path_group_slack_threshold path_group_slack_threshold_num]
[-verbose_level verbose_level_num]
[-feasibility_reporting boolean-string]
```

Data Types

<i>zero_path_margin_num</i>	integer
<i>zero_wire_load_margin_num</i>	integer
<i>io_margin_num</i>	integer
<i>slack_threshold_num</i>	float
<i>path_groups_list</i>	list
<i>path_group_slack_threshold_num</i>	float
<i>verbose_level_num</i>	integer

ARGUMENTS

-enable true | false

A value of true enables the feasibility mode. The default value is false. Feasibility mode is used to identify the timing feasibility of the design and enable constraint relaxation for unachievable endpoints for reporting commands and the place_opt command. The required time at unachievable endpoints are relaxed based on the unachievable timing portion. The following reporting commands honor options set by set_feasibility_options: **report_qor**, **report_qor_snapshot**, **report_timing**, **report_constraints** and **get_timing_paths**. These reporting commands will issue reports based on relaxed constraints at endpoints. The **place_opt** command applies feasibility mode constraint relaxation before starting optimization. Based on the feasibility mode reporting commands and the feasibility mode place_opt command, you can identify feasible and nonfeasible parts of the design. The remaining options to the **set_feasibility_options** command are valid only when the **-enable** option is set to a value of true. When feasibility mode is turned off by using **-enable false**, constraint relaxation is turned off.

-zero_path_violations true | false

A value of true value enables an adjustment to a required time of Zero Path violating endpoints during feasibility place_opt. The required time adjustment for this option is related to the value set by the -

zero_path_margin option. The default value of this option is true. Zero path violations occur when the required time at a path endpoint is equal or smaller than arrival time at the startpoint of the path.

-zero_wire_load_violations true | false

A value of true enable an adjustment to required time of Zero Wire Load violating unachievable endpoints during feasibility place_opt. The required time adjustment for this option is related to the value set by the - **zero_wire_load_margin** option. Setting this option to true does not have any effect if high-fanout net synthesis has not been run on the design. In that case, setting this option will produce a warning message. The default value is true. All Zero Wire Load violations may not be unachievable. If the Zero Wire Load violation is treated as unachievable, then the required time on endpoints is adjusted.

-zero_path_margin zero_path_margin_num

Adds a margin at Zero Path violating endpoints during the feasibility flow. This option is valid only if **-zero_pathViolation** is set to true. The *zero_path_margin_num* is a percentage value added to the required time on top of the absolute value of existing Zero Path Violating slack. The default value is 0. The value of *zero_path_margin_num* should be ≥ 0 . The *zero_path_margin_num* is used to calculate the adjusted required time at endpoints as follows:

$$\text{adjusted required time} = \text{required time} + (1 + \text{zero_path_margin_num}/100)ZP$$

-zero_wire_load_margin zero_wire_load_margin_num

Adds a margin at Zero Wire Load violating endpoints during the feasibility flow. This option is valid only if **-zero_wire_load_violation** is set to true. The *zero_wire_load_margin_num* is a percentage value added to the required time on top of the absolute value of the existing Zero Wire Load Violating slack. The default value is 0. The value of *zero_wire_load_margin_num* should be ≥ 0 . The *zero_wire_load_margin_num* is used to calculate the adjusted required time at endpoints as follows:

$$\text{adjusted required time} = \text{required time} + (1 + \text{zero_wire_load_margin_num}/100)ZWL$$

-io_margin io_margin_num

Enables a margin addition to Input and Output endpoints. The *io_margin_num* is a percentage value added on top of the existing required time value for relaxing the required time at Input and Output endpoints. The default is 0. The value of *io_margin_num* should be ≥ 0 . The *io_margin_num* is used to calculate the adjusted required time at endpoints as follows:

$$\text{adjusted required time} = (1 + \text{io_margin_num}/100) * \text{required time}$$

To ignore Input and Output endpoints during **place_opt** optimization you can set the *io_margin_num* value to a very high number. Limiting optimization on Input and Output endpoints will expose the good, constrained parts of the design for optimization, but in some cases, runtimes might be worse.

-group_io true | false

A value of true groups input and output paths into one path group. The default value is true. If you set this value to false, input and output paths are not grouped. If this option is set to true, and the input and output paths are already in multiple path groups, the tool will create new path groups exclusively for input and output paths.

-design_slack_threshold *slack_threshold_num*

Specifies the slack threshold to be applied to the entire design. The optimization engine will skip endpoints with slack equal to or smaller than the given slack threshold value. The default value is MIN_INT, which means that the default value will not change the optimization behavior. This option is layered, which means you can specify different **design_slack_threshold** values for different layers.

-slack_threshold_path_groups *path_groups_list*

Specifies that endpoints belonging to any path group in the given will be filtered with the slack threshold value given by the -**path_group_slack_threshold** option and this value will override the **design_slack_threshold** value, if given. If the **design_slack_threshold** is not given, then only path_groups that have **slack_threshold_path_groups** given will be affected. No filtering will be done on unspecified path groups. This option must be used in conjunction with **-path_group_slack_threshold** option, otherwise an error will be reported. This option is also layered, so you can specify different values for each path group in different scenarios. To specify different values for different path_groups, simply group those with the same slack threshold and specify those with different slack thresholds in separate calls of the command. If a path group is specified more than once, then the last one to be specified takes effect.

-path_group_slack_threshold *path_group_slack_threshold_num*

The argument is a floating point number and must be used in conjunction with the **-slack_threshold_path_groups** option, otherwise an error will be reported. This option specifies the slack value to be used to filter and adjust the endpoints belonging to path groups specified with the -**slack_threshold_path_groups** option.

-verbose_level *verbose_level_num*

This options allows for additional information to be printed every time the endpoint margins are adjusted according to the feasibility setting. The value of *verbose_level_num* should be ≥ 0 and the default value is 0. Higher settings will cause more information to be printed.

DESCRIPTION

Feasibility mode enables constraint relaxation for unachievable endpoints for reporting commands and the **place_opt** command. During feasibility mode unachievable endpoints are identified and required time on the unachievable endpoints are relaxed based on the unachievable timing portion. Endpoints with Zero path violation and Zero wire load violations are considered unachievable endpoints.

The following reporting commands honor options set by **set_feasibility_options**: **report_qor**, **report_qor_snapshot**, **report_timing**, **report_constraints** and **get_timing_paths**. These reporting commands will report QoR and timing based on relaxed constraint at endpoints. In the **report_timing** command, the adjusted timing and reason is also reported, if applicable. In the **report_qor** command, the report will be two columns, under original constraints and adjusted constraints, respectively. The **place_opt** command applies feasibility mode constraint relaxation before starting optimization. Based on the feasibility mode reporting commands and feasibility mode place_opt, you can identify feasible and non-feasible parts of the design. Feasibility mode also provides the functionality to group Input and Output

paths in separate path group and also ability to relax required time at Input and Output endpoints.

Feasibility mode also enables skipping optimization on endpoints which have slack equal to or smaller than the value specified by the slack threshold argument (either **-design_slack_threshold** or **-path_group_slack_threshold**). The slack threshold functionality should be used on optimized design as this approach is intended to skip endpoints identified to be difficult to optimize after initial optimization.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets zero_path margin to 10% and turns off zero_wire_load violation adjustment and enables feasibility mode:

```
prompt>set_feasibility_options -enable true -zero_path_margin 10 -
zero_wire_loadViolation false
```

The following example turns off zero_path and zero_wire_load violation but adds 20% margin to input and output end points (input and output paths are grouped together as -group_io option is ON by default) and enables feasibility mode:

```
prompt>set_feasibility_options -enable true -zeroPathViolation false -
zeroWireLoadViolation false -ioMargin 20
```

The following example turns on slack threshold filtering:

```
prompt>set_feasibility_options -enable true -designSlackThreshold -10 -
slackThresholdPathGroups "clk1 clk2 path1" -pathGroupSlackThreshold -9
prompt>set_feasibility_options -slackThresholdPathGroups "clk3 clk4 path1" -
pathGroupSlackThreshold -8
```

As the options are additive and overriding, we have the following slack thresholds:

clk1	:	-9
clk2	:	-9
clk3	:	-8
clk4	:	-8
path1	:	-8
other path groups	:	-10

The following example turns off feasibility mode:

```
prompt>set_feasibility_options -enable false
```

set_fix_hold

Sets a **fix_hold** attribute on clocks in the current design.

SYNTAX

```
int set_fix_hold  
clock_list
```

Data Types

clock_list list

ARGUMENTS

clock_list
A list of clocks in the current design.

DESCRIPTION

Creates a **fix_hold** attribute on the named clock objects in the current design. **fix_hold** informs **compile** that hold time violations of the specified clocks should be fixed. To fix a hold violation requires slowing down data signals. **compile** will fix hold violations during the **Fixing Design Rules** step, but only if the maximum delay cost is not increased, or if the **set_cost_priority** command is used to prioritize hold violations ahead of maximum delay cost. **set_fix_hold** can violate setup and fix hold as long as **WNS** is not made worse. **compile** might fix hold and violate setup on non_critical paths.

The **report_clock_attributes** command identifies the clocks that have the **fix_hold** attribute present.

Use the **remove_attribute** command to undo the **set_fix_hold** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command sets a **fix_hold** attribute on clock "clk1".

```
prompt> set_fix_hold clk1
```

The following command removes the **fix_hold** attribute from clock "clk1".

```
prompt> remove_attribute [get_clocks clk1] fix_hold
```

`set_prefer(2)`

set_fix_hold_options

Specifies options for hold fixing during optimization.

SYNTAX

```
int set_fix_hold_options
-default
-prioritize_tns
-prioritize_min
[-preferred_buffer]
```

ARGUMENTS

-default
Specifies default option for hold fixing. The tool rejects any hold fix solution that degrades WNS or max transition. The user may expect some TNS degradation.

-prioritize_tns
Specifies the option to the tool to reject any hold fix solution that degrades TNS (total negative slack) as well as WNS and max transition .The user should be aware that protecting both WNS and TNS sometimes severely restricts hold fixing.

-prioritize_min
Specifies an option to the tool to prioritize min_delay ahead of max_delay. If the user specifies this option, the tool will try more to fix most of the hold violations. The user may observe timing degradation after the hold fixing is performed. The tool can sacrifice max-delay to fix min-delay.This option is recommended only if user wants to fix hold violations aggressively without considering the impact to timing.

DESCRIPTION

This command defines the options to control hold fixing inside place_opt, clock_opt and route_opt. This command enables the user to provide priority between min_delay and max_delay.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to set hold fixing options

```
prompt> set_fix_hold_options -default
prompt> set_fix_hold_options -prioritize_tns
```

SEE ALSO

`set_fix_hold(2)`

set_fix_multiple_port_nets

Sets the **fix_multiple_port_nets** attribute to a specified value on the current design or a list of designs.

SYNTAX

```
int set_fix_multiple_port_nets
    -default | -all
    [-feedthroughs]
    [-outputs]
    [-constants]
    [-buffer_constants]
    [design_list]
```

ARGUMENTS

```
-default
    Removes the fix_multiple_port_nets attribute so that compile will use its default priority, that is no multiple port nets fixing.

-all
    Inserts the same as -feedthroughs -outputs -constants. Note that logic constants are duplicated, not buffered. To buffer logic constants, use the -buffer_constants option with the -all option.

-feedthroughs
    Inserts buffers to isolate input ports from output ports at all levels of the hierarchy.

-outputs
    Inserts buffers so that no cell driver pin drives more than one output port at any level of the hierarchy.

-constants
    Duplicates logic constants so that no constant drives more than one output port at any level of the hierarchy.

-buffer_constants
    Buffers logic constants instead of duplicating them.

design_list
    Specifies a list of designs. The default is the current design.
```

DESCRIPTION

Sets the **fix_multiple_port_nets** attribute on a list of designs. If you do not specify a design list, the current design is used.

This attribute controls whether **compile** inserts extra logic into the design to ensure that there are no feedthroughs, or that there are no two output ports connected to the same net at any level of hierarchy.

The default is not to add any extra logic into the design to fix such cases.

Certain three-state nets cannot be buffered, because this changes the logic functionality of the design.

If **set_fix_multiple_port_nets** is specified more than once on a design, the most recent setting is used and the earlier values are removed. To undo **set_fix_multiple_port_nets**, use the **-default** option, the **remove_attribute** command, or the **reset_design** command.

To view the current setting of the **fix_multiple_port_nets** attribute, use **report_compile_options**.

For some backward compatibility, if **compile** is run on a design with no **fix_multiple_port_nets** attribute and the obsolete variable **compile_fix_multiple_port_nets** is set to true, the attribute is set on the design to correspond with **set_fix_multiple_port_nets -all**. The attribute always has precedence over the variable setting. If **compile** is run when the attribute exists and has a different value than the variable, a warning is printed that the variable is being ignored. Consequently, if the choice of multiple port net fixing has to be changed between two **compile** commands on the same design, the **set_fix_multiple_port_nets** command must be used since changes to the **compile_fix_multiple_port_nets** variable after the first compile will be ignored.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the **fix_multiple_port_nets** attribute so that feedthroughs are buffered and constants are duplicated.

```
prompt> set_fix_multiple_port_nets -feedthroughs -constants
```

The following example sets the **fix_multiple_port_nets** attribute so that multiple outputs and constants are buffered.

```
prompt> set_fix_multiple_port_nets -outputs -buffer_constants
```

set_flip_chip_cell_site

Modifies flip_chip_cell_site properties to set different flip chip driver legal location constraints.

SYNTAX

```
status_value set_flip_chip_cell_site
-flip_chip_site {site_list}
[-personality {personality_list}]
[-
personality_type_constraints {{personality_type max_num} {personality_type max_num}
...}]
[-
reserved_for_cell {{cell_ref {row_index col_index}...} {cell_ref {row_index col_index}...} ...}]
```

Data Types

<i>site_list</i>	collection
<i>personality_list</i>	list
<i>personality_type</i>	string
<i>max_num</i>	integer
<i>cell_ref</i>	collection
<i>row_index</i>	positive integer
<i>col_index</i>	positive integer

ARGUMENTS

```
-flip_chip_site {site_list}
    Specifies a collection of flip chip driver cell sites to be modified.

-personality {personality_list}
    Specifies a list of personality types which are allowed to place in flip chip
    driver ring or array. Each personality type is a string.

-personality_type_constraints {{personality_type max_num} {personality_type
max_num}...}
    Specifies the maximum number of flip chip driver of the particular
    personality type that can be placed in a flip chip driver island. Each driver
    island can have up to five personality constraints. If constraint of a
    personality type is not specified, there will be no limit on the number of
    drivers of such personality type.

-reserved_for_cell {{cell_ref {row_index col_index}...} {cell_ref {row_index
col_index}...} ...}
    Specifies that a certain location pointed by the row and column indices in
    an flip chip driver island is reserved for a certain flip chip driver cell.
    Only the specified flip chip driver can be placed in the location. By default,
    all drivers can be placed on all locations.
```

DESCRIPTION

This command modifies the writable attributes of a selected flip chip cell site, including the site's X and Y dimension, personality type constraint and slots reserved for a certain cell reference.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example changes a flip chip array's dimension to 12 columns and 4 rows. The "blue" type driver can take no more than 4 slots, the "red" type driver can take no more than 6 slots. The slot at row 3 and column 3 is reserved for "ESD" and the slot at column 4 and row 1 is reserved for "SHOULDER".

```
prompt> set_flip_chip_cell_site -flip_chip_site {FC_ARRAY_2}
-priority_type_constraints {{"blue" 4} {"red" 6}} -reserved_for_cell
{{ESD {2 3}} {SHOULDER {4 1}}}
```

SEE ALSO

```
set_flip_chip_driver_ring(2)
set_flip_chip_driver_array(2)
set_flip_chip_driver_island(2)
```

set_flip_chip_driver_array

Defines the legal locations for flip chip driver cells in a matrix configuration.

SYNTAX

```
status_value set_flip_chip_driver_array
-personality_type {personality_type_list}
-max_driver_size {width height}
-start_point start_point
-dimension {col row}
-delta {pitch_x pitch_y}
[-orientation N | W | S | E | FN | FS | FW | FE]
```

Data Types

<i>personality_type_list</i>	list
<i>width</i>	distance
<i>height</i>	distance
<i>start_point</i>	point
<i>col</i>	positive integer
<i>row</i>	positive integer
<i>pitch_x</i>	distance
<i>pitch_y</i>	distance

ARGUMENTS

```
-personality_type {personality_type_list}
    Specifies a list of personality types of flip-chip driver cells to be placed
    in the array. Each personality type is a string name. If unspecified, no
    driver will be placed.

-max_driver_size {width height}
    Specifies the maximum width and height in micron of driver cells that can be
    placed in the array location.

-start_point start_point
    Specifies the lower-left coordinates of the lower left point of the flip chip
    driver array.

-dimension {col row}
    Specifies the dimension of the array.

-delta {pitch_x pitch_y}
    Specifies the pitch of the array in micron: x between columns and y between
    rows.

-orientation N | W | S | E | FN | FS | FW | FE
    Specifies the orientation of drivers placed in the array. Default is the N
    orientation.
        N      rotate 0
        W      rotate 90
        S      rotate 180
```

```
E    rotate 270
FN   rotate 0 and mirror X
FS   rotate 0 and mirror Y
FW   rotate 90 and mirror X
FE   rotate 90 and mirror Y
```

DESCRIPTION

The `set_flip_chip_driver_array` command defines the legal locations for flip chip driver cells in a array configuration. A flip chip driver is the IO driver that connects signal pin to pad pin (flip chip bump).

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example defines legal location for "blue" and "green" type driver cells in 2 columns and 5 row starting at coordinate (100, 100). The spacing between drivers is 80um on either dimension. The largest flip chip driver allowed is 20um by 20um.

```
prompt> set_flip_chip_driver_array -personality_type {"blue" "green"}
          -max_driver_size {20 20} -start_point {100 100} -dimension {2 5} -delta {80 80}
```

SEE ALSO

`set_flip_chip_driver_ring(2)`
`set_flip_chip_driver_island(2)`

set_flip_chip_driver_island

Defines the legal locations to place flip chip drivers in an island style.

SYNTAX

```
status_value set_flip_chip_driver_island
-start_point start_point
-repeat {num_columns num_rows}
-spacing {x_spacing y_spacing}
-island_size {width height}
-num_driver {num_x num_y}
[-filler cell_ref]
[-
personality_type_constraints {{personality_type max_num} {personality_type max_num} ...}]
[-default_orientation N | W | S | E | FN | FE | FS | FW]
[-orient_by_row]
[-compaction vertical | horizontal | none]
[-center_packing]
[-forced_orientation {{orientation col_index} {orientation col_index} ...}]
[-reserved_for_cell {{cell_ref col_index row_index}...} {cell_ref col_index row_index}...} ...}]
```

Data Types

<i>start_point</i>	point
<i>num_columns</i>	positive integer
<i>num_rows</i>	positive integer
<i>x_spacing</i>	distance
<i>y_spacing</i>	distance
<i>width</i>	distance
<i>height</i>	distance
<i>num_x</i>	positive integer
<i>num_y</i>	positive integer
<i>cell_ref</i>	collection
<i>personality_type</i>	string
<i>max_num</i>	positive integer
<i>orientation</i>	N W S E FN FE FS FW
<i>col_index</i>	positive integer
<i>row_index</i>	positive integer

ARGUMENTS

-start_point *start_point*

Specifies the lower-left coordinates of the first (bottom-left) island.

-repeat {*num_columns num_rows*}

Specifies the number of rows and columns of the flip chip island array.

-spacing {*x_spacing y_spacing*}

Specifies the X and Y spacing between two adjacent flip chip driver islands.

set_flip_chip_driver_island

2286

The unit is in micron.

-island_size {width height}

Specifies the width and height of each flip chip driver island. The unit is in micron.

-num_driver {num_x num_y}

Specifies the number of flip chip drivers that can be placed in the X and Y direction of each island.

-filler cell_ref

Specifies a cell reference to be used as filler for empty space in the island when the flip chip driver compaction operation is performed. The cell_ref collection must contain one cell reference of the cell library.

-personality_type_constraints {{personality_type max_num} {personality_type max_num} ...}

Specifies the maximum number of flip chip driver of the particular personality type that can be placed in a flip chip driver island. Each island can have up to five personality constraints. If constraint of a personality type is not specified, there will be no limit on the number of drivers of such personality type.

-default_orientation N | W | S | E | FN | FE | FS | FW

Specifies the orientation of flip chip driver when placed. Default is N.

-orient_by_row

Specifies the forced orientation of the drivers are set by rows. If this option is used together with -forced_orientation option, the col_index will indicate row_index in practice. By default, the forced orientations of the drivers are set by rows.

-compaction vertical | horizontal | none

Specifies the flip chip island compaction direction. Compaction also shrinks the island size to make room for standard cells placement. If this option is not specified, a vertical compaction will be performed.

-center_packing

Forced the flip chip drivers to be packed towards the center of the island. The default packing orientation depends on the orientation of the drivers.

-forced_orientation {{orientation col_index} {orientation col_index} ...}

Forced a certain orientation on a flip chip driver placed on the specified column. The orientation is one of the values in {N | W | S | E | FN | FE | FS | FW }. If the -orient_by_row option is used, specify the row index position in this option instead of the column index position.

[-reserved_for_cell {{cell_ref {col_index row_index}...} {cell_ref {col_index row_index}...} ...}]

Specifies that a certain location pointed by the row and column indices in an island is reserved for a certain flip chip driver cell. Only the specified flip chip driver can be placed in the location. By default, all drivers can be placed on all locations.

DESCRIPTION

Defines flip chip cell sites that form the legal locations for flip chip drivers to be placed in an island fashion. An island can contain a two dimensional array of flip chip driver slots. Each slot can hold a flip chip driver. This command creates the flip chip cell sites and also defines constraints on flip chip driver placement.

allows you to define an array of islands while minimizing the number of filler cells inserted in each island..

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates an array of 20 by 20 (400) flip chip driver islands starting at coordinates (300, 600). The islands have spacing of 100um in either directions and the size of each island is 30um by 30um. Each island is capable of holding 9 rows by 2 columns of flip chip drivers. The first and last row of each island is reserved for cell "SHOULDER". The eighth row of the island is reserved for cell "ESD". The flip chip drivers on column 1 will be at the W orientation and that on column 2 will be at the FW orientation. Compaction will be performed in the vertical direction after driver placement.

```
prompt> set_flip_chip_driver_island -start_point {300 600} -repeat {20 20}
-priority_type_constraints {{"red" 10} {"green" 15}}
-spacing {100 100} -island_size {30 30} -num_driver {2 9} -filler {"DUMMY"} -
forced_orientation {{W 1} {FW 2}} -
reserved_for_cell {{"SHOULDER" {1 1} {2 1} {1 9} {2 9}} {"ESD" {1 8} {2 8}}}
1
```

SEE ALSO

`set_flip_chip_driver_ring(2)`
`set_flip_chip_driver_array(2)`
`set_flip_chip_options(2)`

set_flip_chip_driver_ring

Defines the legal locations for flip chip driver cells in a ring configuration.

SYNTAX

```
status_value set_flip_chip_driver_ring
-personality_type {personality_type_list}
-max_driver_size {width height}
-max_driver_num_per_ring driver_num
-min_driver_spacing driver_spacing
-ring_number ring_number
-ring_spacing ring_spacing
-outer_ring boundary_box
[-orientation N | W | S | E | FN | FS | FW | FE]
[-num_extra_spacing num_extra]
[-extra_spacing extra_spacing]
[-stagger_drivers]
```

Data Types

<i>personality_type_list</i>	list
<i>width</i>	distance
<i>height</i>	distance
<i>driver_num</i>	positive integer
<i>driver_spacing</i>	distance
<i>ring_number</i>	positive integer
<i>ring_spacing</i>	distance
<i>boundary_box</i>	rectangle
<i>num_extra</i>	positive integer
<i>extra_spacing</i>	distance

ARGUMENTS

- personality_type {personality_type_list}
Specifies a list of personality types of flip-chip driver cells to be placed in the rings. Each personality type is a string name. If unspecified, no driver will be placed.
- max_driver_size {width height}
Specifies the maximum width and height in micron of driver cells that can be placed in the rings.
- max_driver_num_per_ring driver_num
Specifies the maximum number of drivers allowed in each ring.
- min_driver_spacing driver_spacing
Specifies the minimum spacing between adjacent driver cells of the same ring in micron.
- ring_number ring_number
Specifies the number of rings to be created.

-ring_spacing *ring_spacing*
 Specifies the spacing between adjacent rings in micron.

-outer_ring *boundary_box*
 Specifies the lower-left coordinate {llx lly} and up-right coordinate {urx ury} of the bounding box of the outermost ring in the format of {{llx lly} {urx ury}}.

-orientation N | W | S | E | FN | FS | FW | FE
 Specifies the orientation of drivers placed on the left edge of the ring. The top, right and bottom edge have an additional 90, 180 and 270 degrees of rotation respectively. Default is the N orientation.

N	rotate 0
W	rotate 90
S	rotate 180
E	rotate 270
FN	rotate 0 and mirror X
FS	rotate 0 and mirror Y
FW	rotate 90 and mirror X
FE	rotate 90 and mirror Y

-num_extra_spacing *num_extra*
 Specifies the size of driver cell group for which additional spacing is inserted. This option should be used together with the -extra_spacing option to specify, for example, an addition spacing of 10um for every 5 driver cells. By default, there will be no additional spacing.

-extra_spacing *extra_spacing*
 Specifies additional spacing for a group of driver cells in micron. This option must be used together with -num_extra_spacing option to specify, for example, an addition spacing of 10um for every 5 driver cells. By default, there will be no additional spacing.

-stagger_drivers
 This option creates a staggered flip chip driver placement in the even numbered ring. The tool places drivers on every other ring with an offset given by half of the sum of minimum driver spacing and driver width.

DESCRIPTION

This command defines the legal locations for flip chip driver cells in a ring configuration. A flip chip driver is a special cell that connects to a flip chip bump. This command is used for peripheral I/O style of flip chip driver placement where the drivers are placed on the four sides of a chip.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example defines ring style legal location constraint for flip chip drivers with the "blue" and "green" personality type if their sizes are smaller than 20um in width and 100um in height. Flip chip drivers are placed in two rings with the outer most ring at coordinate (100, 100) (900, 900) and a spacing of 15.0um between the two rings. Each ring can hold at most 150 drivers with a minimum spacing of 1.2um between two adjacent drivers of the same ring.

```
prompt> set_flip_chip_driver_ring\
-personality_type {"blue" "green"}\
-max_driver_size {20 100}\
-max_driver_num_per_ring 150\
-min_driver_spacing 1.2\
-ring_number 2 -ring_spacing 15.0\
-outer_ring {{100 100}{900 900}}
```

SEE ALSO

`set_flip_chip_driver_array(2)`
`set_flip_chip_driver_island(2)`

set_flip_chip_grid

Creates equally spaced grid points for flip chip driver placement.

SYNTAX

```
status_value set_flip_chip_grid
-grid_origin {llx lly}
-x_step x
-y_step y
```

Data Types

llx	distance
lly	distance
x	distance
y	distance

ARGUMENTS

```
-grid_origin {llx lly}
    Specifies the lower-left coordinates in microns for the flip chip grid.

-x_step x
    Specifies the spacing of the grid in the X-direction in microns.

-y_step y
    Specifies the spacing of the grid in the Y-direction in microns.
```

DESCRIPTION

This command defines a secondary placement grid for flip chip drivers that is usually different from the placement grid used by standard cells. A flip chip driver must be placed on the secondary placement grid. In addition, all flip chip driver legal location sites must be on this secondary placement grid.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the secondary flip chip placement grid starting at (0,0) with 10um spacing:

```
prompt> set_flip_chip_grid - grid_origin {0 0} -x_step 10 -y_step 10
```

SEE ALSO

`set_flip_chip_driver_island(2)`

`set_flip_chip_grid`
2292

```
set_flip_chip_driver_array(2)
set_flip_chip_driver_ring(2)
```

set_flip_chip_options

Sets general flip-chip driver placement options during virtual flat placement.

SYNTAX

```
status_value set_flip_chip_options
[-disable_driver_placement]
[-package_driven]
[-one_softmacro_per_island]
[-flip_chip_net_weight weight]
[-softmacro_net_weight sm_weight]
[-guardband_width {x y}]
[-multiple width | height | both]
```

Data Types

<i>weight</i>	integer from 1 to 1000
<i>sm_weight</i>	integer from 1 to 1000
<i>x</i>	distance
<i>y</i>	distance

ARGUMENTS

-disable_driver_placement
Disables flip chip driver placement. Drivers will not be moved when standard cells are placed.

-package_driven
Enables the package driven placement flow. Use this option when flip chip driver to bump connections already exist and you want drivers to be placed as close as possible to their matching bumps. If this option is specified, the "-one_softmacro_per_island" cannot be used.

-one_softmacro_per_island
Instructs the tool to place flip chip drivers connected to the same soft macro on the same flip chip driver island. Other drivers not connected to the soft macros will not be placed on the island. If this option is specified, the "-package_driven" option cannot be used

-flip_chip_net_weight *weight*
Sets the net weights on the nets between the drivers and the bumps. Default net weight is 1 if not specified, giving equal consideration between the flip chip nets and a regular signal net. Weight value from 1 to 1000 can be given. The higher weight of a flip chip net indicates the higher cost of the same wire length than regular signal net, i.e the tool will try harder to place the drivers and bumps close.

-softmacro_net_weight *sm_weight*
Sets the net weights on nets connecting drivers and soft macros. Default net weight is one if not specified, giving equal consideration between the flip chip nets and a regular signal net. Weight value from 1 to 1000 can be given. The higher weight of a flip chip net indicates the higher cost of the same

wire length than regular signal net, i.e the tool will try harder to place the drivers and soft macros close.

-guardband_width {x y}

Sets the guardband of a flip chip island in the X and Y directions in micron. If not specified, the old value will be used. If never set before, 0 will be given as default value.

-multiple width | height | both

Allows drivers whose height or width or both is greater than a flip chip slot size to be placed inside the island. A driver will consume more than one slot in an island. Default is not allow multiple of either.

DESCRIPTION

Sets various options related to flip chip flow. The settings are Milkyway persistent and will be honored through out the design flow. A flip chip island is a cell site for flip chip drivers placement. An island is further partitioned into a two dimensional array of slots as defined by the `set_flip_chip_driver_island` command. Each slot can hold a unit sized flip chip driver. A flip chip driver is used to send or receive off-chip signal through a flip chip bump. A flip chip bump is a piece of top level metal that forms electrical connection to the chip package. Standard cells may overlap with a flip chip bump but not allowed with a flip chip driver.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the package driven flow and sets a 4um guardband on either directions of a flip chip island.

```
prompt> set_flip_chip_options -package_driven -guardband_width {4 4}
1
```

SEE ALSO

`set_flip_chip_driver_island(2)`

set_flip_chip_type

Assigns personality types to specified nets, flip chip bumps or drivers.

SYNTAX

```
status_value set_flip_chip_type
-personality_type type
net_or_cell_list
```

Data Types

<i>type</i>	string
<i>net_or_cell_list</i>	collection

ARGUMENTS

-personality_type *type*

Specifies the personality type to be assigned to nets or cells.

net_or_cell_list

Specifies a collection of nets or cells where personality type will be assigned. The collection must contain nets, flip chip drivers or flip chip bumps.

DESCRIPTION

This command assigns personality types to specified nets, bumps or drivers.

In a flip chip design, a bump is a piece of metal at the topmost layer of the chip that forms an electrical contact to the chip's packaging. A flip chip driver is an I/O circuitry that drives or receives signals from or to the chip thru the bump. A bump and its associated driver may be placed at different locations but need to be electrically connected.

A personality type is a string associated to a net or a flip chip driver or a flip chip bump. Only drivers and bumps of identical personality type can be electrically connected to form a complete I/O circuit. Drivers and bumps without a personality type setting will have a default personality type, which is an empty string. The personality type settings are stored in the design and are Milkyway persistent. This command can be issued multiple times. A new personality type setting overrides an existing personality type setting.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the instances "DRIVER_%" with the "red" personality type:

```
set_flip_chip_type
2296
```

```
prompt> set_flip_chip_type -personality_type "red" {"DRIVER_*"}
```

SEE ALSO

`report_flip_chip_type(2)`
`assign_flip_chip_nets(2)`

set_fp_base_gate

Sets either a library leaf cell area or a user-specified cell area as the base unit area to use for gate equivalence calculations related to estimating the size of black boxes.

SYNTAX

```
status set_fp_base_gate
{-cell master_name | -area cell_area}
```

ARGUMENTS

-cell *master_name*
Specifies the master name of the library leaf cell to use as the base unit area for gate equivalence calculations.

-area *cell_area*
Specifies the cell area in square microns to use as the base unit area for gate equivalence calculations.

DESCRIPTION

Sets either a library leaf cell area or a user designated cell area as the base unit area to use for gate equivalence calculations related to estimating the size of black boxes.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

Set base gate area to cell master UNIT

```
prompt> set_fp_base_gate -cell UNIT
```

Set base gate area to 10 square microns

```
prompt> set_fp_base_gate -area 10
```

SEE ALSO

`estimate_fp_black_boxes(2)`
`import_fp_black_boxes(2)`

set_fp_black_boxes_estimated

Sets the specified objects as estimated so that they are flagged as not needing to be sized before floorplanning.

SYNTAX

```
status set_fp_black_boxes_estimated  
black_boxes
```

ARGUMENTS

```
black_boxes  
    black boxes to set estimated
```

DESCRIPTION

Specifies that the supplied black box objects have been estimated and so are valid for floorplanning.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

Set alu1 black box state to estimated

```
> set_fp_black_boxes_estimated [get_cells alu1]
```

SEE ALSO

```
set_fp_black_boxes_unestimated(2)  
get_cells(2)
```

set_fp_black_boxes_unestimated

Sets the specified objects as unestimated so that they are flagged as needing to be sized correctly before floorplanning.

SYNTAX

```
status set_fp_black_boxes_unestimated  
black_boxes
```

ARGUMENTS

```
black_boxes  
    black boxes to set unestimated
```

DESCRIPTION

Sets the specified objects as unestimated so that they are flagged as needing to be sized correctly before floorplanning.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
Set alu1 black box state to unestimated
```

```
> set_fp_black_boxes_unestimated [get_cells alu1]
```

SEE ALSO

```
set_fp_black_boxes_estimated(2)  
get_cells(2)
```

set_fp_block_ring_constraints

Defines the power and ground rings that are automatically created around plan groups and macros when power network straps are synthesized by power network synthesis (PNS).

SYNTAX

```
status set_fp_block_ring_constraints
-add
  | -remove
  | -remove_all
  | -save_file file_name
  | -load_file file_name
[-block_type master | instance | plan_group | voltage_area]
-block blocks
[-all_blocks]
-nets nets
[-horizontal_layer layer]
[-vertical_layer layer]
[-horizontal_width distance]
[-vertical_width distance]
[-horizontal_offset distance]
[-vertical_offset distance]
[-spacing distance]
```

Data Types

<i>file_name</i>	string
<i>blocks</i>	collection or list
<i>nets</i>	collection or list

ARGUMENTS

```
-add
    Add or update block ring constraints.
    This option is mutually exclusive with the -remove, -remove_all, -load_file, and -save_file options; you must specify only one.

-remove
    Remove the specified block ring constraints.
    This option is mutually exclusive with the -add, -remove_all, -load_file, and -save_file options; you must specify only one.

-remove_all
    Remove all block ring constraints.
    This option is mutually exclusive with the -add, -remove, -load_file, and -save_file options; you must specify only one.

-save_file file_name
    Saves the block ring constraints in the specified file.
    This option is mutually exclusive with the -add, -remove, -remove_all and -load_file options; you can specify only one.
```

```

-load_file file_name
    Loads the block rings constraints from the specified file.
    This option is mutually exclusive with the -add, -remove, -remove_all and -save_file options; you can specify only one.

-block_type master | instance | plan_group | voltage_area
    Identifies the type of block specified in the -block option.
    If you specify master, rings are created around all instances that use the specified reference cells.
    If you specify instance, rings are created around the specified cell instances.
    If you specify plan_group, rings are created around the specified plan groups.
    If you specify voltage_area, rings are created around the specified voltage areas.
    The default type is 'master'.

-block blocks
    Specifies the blocks for which power and ground rings are created.
    There is no default value; you must specify this option.
    If you specify multiple blocks, power and ground rings are created for each block. For example, to create power and ground rings for blocks B1, B2, B3 and B4, enter -block {B1 B2 B3 B4}.

-all_blocks
    For a given block type, specifies all the blocks for power and ground ring creation.

-nets nets
    Specifies the power and ground nets used for the generated rings.
    There is no default value; you must specify this option.
    If you specify multiple nets, multiple rings are created around the specified blocks. The first net is the innermost block ring. For example, to create four rings, enter -nets {VDD1 VSS1 VDD2 VSS2}.

-horizontal_layer layer
    Specifies the horizontal layer for the block ring. You can specify only one horizontal layer per block ring constraint.
    The default is the highest layer with preferred horizontal direction.

-vertical_layer layer
    Specifies the vertical layer for the block ring. You can specify only one vertical layer per block ring constraint.
    The default is the highest layer with preferred vertical direction.

-horizontal_width distance
    Specifies the width (in microns) of the horizontal wires.
    The default is the minimum width defined in the technology file.

-vertical_width distance
    Specifies the width (in microns) of the vertical wires.
    The default is the minimum width defined in the technology file.

-horizontal_offset distance
    Specifies the horizontal offset (in microns) from the block boundary to the

```

```

block ring.
The default value is the minimum horizontal spacing defined in the technology
file.

-vertical_offset distance
    Specifies the vertical offset (in microns) from the block boundary to the
    block ring.
    The default value is the minimum vertical spacing defined in the technology
    file.

-spacing distance
    Specifies the spacing between block rings.
    The default value is the minimum spacing defined in the technology file.

```

DESCRIPTION

This command defines the power and ground rings that are created around the specified blocks (macros or plan groups) when power network straps are synthesized by power network synthesis (PNS). Rectangular and rectilinear rings are supported.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to create power rings for the VDD net around all blocks with the R16X16M1 reference cell. The power ring is created on horizontal layer METAL5 with a ring width of 1.0 micron and an offset of 0.6 micron and on vertical layer METAL6 with a ring width of 1.0 micron and an offset of 0.6 microns.

```

prompt> set_fp_block_ring_constraints \
    -add \
    -block_type master \
    -block R16X16M1 \
    -horizontal_layer METAL5 \
    -horizontal_width 1.0 \
    -vertical_layer METAL6 \
    -vertical_width 1.0 \
    -horizontal_offset 0.6 \
    -vertical_offset 0.6 \
    -nets VDD

```

SEE ALSO

`set_fp_rail_constraints(2)`
`report_fp_rail_constraints(2)`
`synthesize_fp_rail(2)`

set_fp_clock_plan_options

Sets options for the clock planning clock tree synthesis engine.

SYNTAX

```
status set_fp_clock_plan_options
[-output_directory directory]
[-no_feeds_plan_group plan_groups]
[-clock_nets clock_nets]
-anchor_cell cell
[-route_mode detailed | global | none]
[-keep_block_tree true | false]
```

Data Types

<i>directory</i>	string
<i>plan_groups</i>	collection
<i>clock_nets</i>	collection
<i>cell</i>	collection

ARGUMENTS

```
-output_directory directory
    Specifies the directory in which to write all constraint files, log files,
    and reports. By default, the tool uses a directory called cp_output.

-no_feeds_plan_group plan_groups
    Specifies a list of plan groups in which feedthroughs are not allowed. By
    default, feedthroughs are allowed in all plan groups.

-clock_nets clock_nets
    Specifies a list of clock nets on which to do clock planning.

-anchor_cell cell
    Specifies a list of the cells that are inserted as the anchor cells for all
    plan groups. By default, the tool generates an error message.

-route_mode detailed | global | none
    Specifies the type of routing to be performed on top-level clock nets. Use
    detailed to perform detailed routing on top-level clock nets. Use global to
    perform global routing. Use none to perform no routing. By default, the tool
    performs no routing.

-keep_block_tree true | false
    Specifies whether the block-level clock tree built during clock planning will
    be kept. Use true to keep that block-level clock tree. Use false to remove
    this block-level clock tree when clock planning is finished. By default, the
    tool removes this block-level clock tree when clock planning is finished.
```

DESCRIPTION

This command sets the proper environment before running the **compile_fp_clock_plan** command. For best results, specify **-no_feeds_plan_group** for all plan groups on which clock planning is performed.

The anchor cell is the buffer cell that is inserted in each plan group. All plan groups should use the same buffer type. Clock planning supports only buffer cells as anchor cells (inverters are not supported as anchor cells). You can use the **report_fp_clock_plan_options** command to report clock planning settings.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLE

The following example sets the output directory to the name tmp_dir.

```
prompt> set_fp_clock_plan_options\
-output_directory tmp_dir
```

The following example specifies the plan groups in which feedthroughs are not allowed.

```
prompt> set_fp_clock_plan_options\
-no_feed_plan_groups [get_plan_groups *]
```

The following example sets the anchor cell to the name CLKBUF12 and selects global routing for the top-level clock nets.

```
prompt> set_fp_clock_plan_options\
-clocks_nets CLK1 -anchor_cell CLKBUF12\
-route_mode global
```

SEE ALSO

compile_fp_clock_plan(2)
report_fp_clock_plan_options(2)

```

set_fp_flow_strategy
    Sets the strategy for the hierarchical flow. These settings are not persistent
    in the Milkyway database.
    status set_fp_flow_strategy
        [-plan_group_aware_routing true | false]
        [-top_level_routing_only true | false]

-plan_group_aware_routing true | false
    When set to true, the subsequent route_global, route_fp_proto, and
    place_fp_pins commands read any plan group definitions and honor any
    constraints placed on the plan groups, such as prohibitions on feedthroughs,
    TDF constraints, or pin blockages.
    When set to false, the subsequent route_global, route_fp_proto, and
    place_fp_pins commands will not read in any plan group definitions. Routing
    is run without any awareness of the plan groups and therefore, any constraints
    placed on the plan groups will have no effect.
    When routing is "plan group-aware", it not only honors any special
    constraints placed on the plan groups such as pin spacing or TDF constraints,
    but it also enforces the hierarchy rules for boundary crossings. For example,
    an intra-plan group net (a net that has connections only inside a plan group)
    is not allowed to cross the plan group boundary but must be routed entirely
    within the plan group.
    When this flag is enabled it also gives priority to clock nets. While
    floorplanning you may want to route the clock "flat" to generate clock pins
    on module boundaries. Of course, these clock should be buffered later. The
    clock nets will be routed before any other nets so that their pin placement
    has priority over normal signal pins.
    In the virtual flat or pin cutting flow, you MUST set this value to true. If
    you route without awareness of plan groups, the analyze_fp_routing and
    commit_fp_plan_groups commands will not work properly.
    This argument can affect the place_fp_pins command if, in addition to the
    soft macros for which you are placing pins, there are uncommitted plan groups.
    In this case, it may be important to take the plan groups into account. For
    example, if feedthroughs on the plan groups are prohibited, you want the soft
    macro pin placement to take that into account.
    The default value is false.

-top_level_routing_only true | false
    When set to true, the subsequent route_global, route_fp_proto, and
    place_fp_pins commands will not route any nets that are entirely contained
    within plan groups. Note that for this option to be effective, the -
    plan_group_aware_routing must also be set to a value of true.
    The purpose of the Ø op_level_routing_only option is to increase routing
    speed. Intra-plan group routing is not strictly needed for creating
    feedthroughs and pin positions in the subsequent analyze_fp_routing and
    commit_fp_plan_group commands. However, if routing congestion inside the plan
    groups is significant, ignoring the intra-plan group nets could lower the
    quality of the pin placement.
    When set to false the subsequent route_global, route_fp_proto, and
    place_fp_pins pins will route all signal nets.
    This command sets parameters that affect the strategy for the hierarchical
    floorplanning flow.
    The settings for this command are valid in the current session only.

```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

In the following example, the router will read in the plan group definitions, enabling the constraint prohibiting feedthroughs on plan groups to be effective.

```
prompt> set_fp_flow_strategy -plan_group_aware_routing true prompt> set_fp_pin_constraints -allow_feedthroughs off
prompt> route_global
```

In the following example, the router will not read in the plan group definitions. Therefore the constraint prohibiting feedthroughs on plan groups will have no effect. The router will run in its normal "flat" mode, without any regard for plan group boundaries.

```
prompt> set_fp_flow_strategy plan_group_aware_routing false prompt> set_fp_pin_constraints -allow_feedthroughs off
prompt> route_global
```

In the following example, the router will read in the plan group definitions and will not route any nets that are entirely contained within single plan groups (intra-plan group nets). Note that the rest of the flow including analyze_fp_routing and commit_fp_plan_groups does not require intra-plan group routing, so it is unaffected by this parameter (with the exception for any impact on the quality of results).

```
prompt> set_fp_flow_strategy -plan_group_aware_routing true
prompt> -top_level_routing_only true route_global
prompt> analyze_fp_routing -finalize_pins_and_feedthroughs
prompt> plan_groups commit_fp_plan_groups
route_global(2)
route_fp_proto(2)
set_fp_pin_constraints(2)
analyze_fp_routing(2)
commit_fp_plan_groups(2)
place_fp_pins(2)
```

set_fp_macro_array

Specifies an array of macro cells.

SYNTAX

```
status set_fp_macro_array
-name string
[-elements collection_of_macro_cell_objects]
[-align_edge t | b | l | r | c | top | bottom | left | right | center]
[-align_pins {list of two pin objects}]
[-x_offset float]
[-y_offset float]
[-use_keepout_margin]
[-vertical]
[-rectilinear]
[-align_2d lb | lc | lt | rb | rc | rt | cb | cc | cr | left-bottom | left-
center | left-top | right-bottom | right-center | right-top | center-
bottom | center-center | center-top]
[-reset]
```

ARGUMENTS

-name *string*

Specifies name for the macro array.

-elements *collection_of_macro_cell_objects*

This option specifies a collection or list-of_collection of macro cells which will compose the array. Each sub list represents a row in the array. An array starts from top most row. A row starts from left. For example, to specify an array like following

A11 A12 A13

A21 A22 A23

A31 A32 A33

```
-elements [list [get_cells "A11 A12 A13"] \
           [get_cells "A21 A22 A23"] \
           [get_cells "A31 A32 A33"]]
```

This is required when creating a macro array. It is not required when -reset option is used to remove a macro array.

-align_edge t | b | l | r | c | top | bottom | left | right | center

Specifies an edge for the macro cells in one row to align with. Default is to align to the centers.

-align_pins {list of two pin objects}

Align two macro cells with pins. In the list, the first pin is a pin on reference cell (first cell in the array) and the second pin is a pin from second cell. This option takes effect only if specified array has two macro cells.

-x_offset *float*

Specifies the distance between two adjacent edges of macro cells on one row. Unit is micron. Default value is 0, which means the cells will abut to each

other.

-y_offset float

Specifies the distance between two adjacent edges of macro cells on the same column of the next row. Unit is micron. Default value is 0, which means the cells will abut to each other.

-use_keepout_margin

Specifies the tool to use keepout margin to determine the spacing between two adjacent rows and/or columns of the array. This option is mutually exclusive with -x_offset and -y_offset options.

-vertical

If specified for one dimensional array, it causes the command to arrange one dimensional macros in a vertical column. By default these arrays are created as horizontal rows. If specified for two dimensional array, it causes the tool to arrange the array in column based structure, instead of row based structure. It is like rotate a two dimensional array 90 degrees counter-clock-wise.

-rectilinear

This option is for 2D array. It specifies that the overall shape of the 2D array is rectilinear. For a rectilinear macro array, you can specify different number of cells in different rows. By default, in design planning, a 2D macro array is placed as a single object that is rectangular in shape, and all the rows(or columns) in the array have the same number of cells.

-align_2d lb | lc | lt | rb | rc | rt | cb | cc | cr | left-bottom | left-center | left-top | right-bottom | right-center | right-top | center-bottom | center-center | center-top

"left-bottom | left-center | left-top | right-bottom | right-center | right-top | center-bottom | center-center | center-top" This option is for heterogeneous 2D array. It specified edges for the macro cells in a row or column to align with in a heterogeneous 2D macro array. This option is not mandatory. Default is to align the cells in the same column by their left edge, and align the cells in the same row by their bottom edge.

-reset

Removes the macro array constraint. This option is mutually exclusive with all other options except for -name.

DESCRIPTION

The **set_fp_macro_array** command Defines an array of macro cells. The tool places macro cells in the array according to the parameters specified for the array.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to specify a 2x2 array for cell A11 A12 A21 A22 with 10 microns space between rows and columns.

```
prompt>set_fp_macro_array
        -name AA
        -elements [list [get_cells "A11 A12"]
                    [get_cells "A21 A22"]]
        -x_offset 10
        -y_offset 10
```

The following example shows how to remove a previously defined macro array ICRAMARR AY1.

```
prompt>set_fp_macro_array -name ICRAMARRAY1 -reset
```

SEE ALSO

`create_fp_placement(2)`
`set_fp_macro_options(2)`

set_fp_macro_options

Specifies constraints on the specific floorplan macro cells and macro arrays in design planning.

SYNTAX

```
status set_fp_macro_options
collection_of_macro_objects
[-legal_orientations list]
[-anchor_bound {tl | t | tr | r | br | b | bl | l | tm | bm | lm | rm | c}]
[-x_offset float]
[-y_offset float]
[-align_pins list]
[-side_channel {left_right_top_bottom}]
[-reset]
```

ARGUMENTS

collection_of_macro_objects

This option specifies a collection of macro cells the command applies to. Use the **get_cell** command to obtain the macro cell object. For example, [**get_cell Input***]. You can also specify macro array names to constraint them using the above switches.

-legal_orientations list

Specify the legal orientation of the macro cells so that the placement tool will optimize the macro cell orientation within the defined values of the -legal_orientations option. The value can be one or more than one of the 8 possible orientations represented by following strings.

DEF syntax: N, W, S, E, FN, FW, FS, FE

If user does not specify this option, then the macro cell's library legal orientations will be used in the placement. Otherwise, the common sub-set of orientations that are allowed by this option and the macro cell's library will be used in the placement. If the orientations specified by this option conflicts with library which results an empty common sub-set, orientation constraint specified by this option will be ignored, and placement will use the library legal orientations.

User can specify a single legal orientation to force the placer to place the cell in the fixed orientation.

User cannot specify orientation for macro arrays.

-anchor_bound {tl | t | tr | r | br | b | bl | l | tm | bm | lm | rm | c}

Specifies a macro cell's anchor bound (a kind of placement move bound).

The valid keywords and their definitions are shown below:

Keyword Definition

----- -----

tl	top-left corner
t	top
tr	top-right corner
r	right
br	bottom-right corner
b	bottom

bl	bottom-left corner
l	left
tm	top-middle
bm	bottom-middle
lm	left-middle
rm	right-middle
c	center

This anchor bound constrains the placement tool so that it places the macro cell in one of the boundary areas of the block. This forces the macro cell to stay at one of the boundaries of the block. The default move bound will be one-half or one-quarter of the core area associated with the specified anchor boundary. For example, if you specify `-anchor_bound` as **t**, the move bound will be the top half of the core area. If you specify `-anchor_bound` as **tr**, the move bound will be the top-right area of the core area. If the one-half or one-quarter core area is not large enough to hold the macro cell, with any set of dimensions, the move bound is set to cell width or height in that dimension.

The type of the `-anchor_bound` is SOFT, which means that placement can always move the macro cell out of the bound in case there is no space and the cost is too high.

You can specify `-anchor_bound` for macro arrays.

-x_offset float

-y_offset float

Specifies the distance between the constrained element and the core edges. If the `-anchor_bound` is **t**, **b** **tm** or **bm**, user should specify only `-y_offset`. If the `-anchor_bound` is **l**, **r**, **lm** or **rm**, user should specify only `-x_offset`. If the `-anchor_bound` is **tl**, **tr**, **bl** or **br**, user can specify `-x_offset` or `-y_offset` or both.

-align_pins list

Aligns a specific port to a pin of constrained macro cell. The argument passed with this switch is a list of two pins; reference pin followed by constrained pin. For example, `set_fp_macro_options [get_cell A1] -anchor_bound t -align_pins [list [get_ports "PD[0]"] [get_pins "A1/DATA[0]"]]`.

-side_channel {left_right_top_bottom}

Specify this when you want to place the macro at least some distances away from the core edge.

-reset

Removes the constraints set with previous uses of the **set_fp_macro_options** command.

DESCRIPTION

The **set_fp_macro_options** command sets the constraints for the macro cell and macro array for virtual flat placement. The command constrains the **create_fp_placement** command in placing the macro cells in the floorplan. You use this command before **create_fp_placement**. Use this command after you load the design.

You can use this command to restrict macro cells and macro arrays in different ways:

set_fp_macro_options

2312

- To a particular region, by specifying the `-anchor_bound` option.
- During the macro cell placement, by constraining with the `-legal_orientation` option, and the library legal orientations. Macro cell orientation must be one of the legal orientations.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to place the cell RAM1 only on the top-right corner of the core area and in south orientation.

```
prompt>set_fp_macro_options [get_cell "RAM1"] \
-legal_orientation S -anchor_bound tr
```

The following example shows how to place the user defined macro array ICRamMacroArray1 to the bottom-left corner of the core area.

```
prompt>set_fp_macro_options ICRamMacroArray1 \
-anchor_bound bl
```

The following example shows how to place the user defined macro array ICRamMacroArray2 at least 20 microns away from the left edge of the core area, 30 microns from its right edge, and 30 microns from its top edge.

```
prompt>set_fp_macro_options \
-side_channel {20 30 30 0} ICRamMacroArray2
```

```

Data Types

<i>layers</i>	collection
<i>pin_spacing_number</i>	integer
<i>preoute_spacing_number</i>	integer
<i>wiretracks_number</i>	integer
<i>keepout_percentage</i>	real
<i>side_numbers</i>	string
<i>hfn_number</i>	integer
<i>nets</i>	collection
<i>skip_number</i>	integer
<i>blocks</i>	collection

ARGUMENTS

-allowed_layers *layers*

Specifies the set of metal layers allowed for pin placement. The argument is a collection of consecutive metal layers. A collection that contains nonconsecutive metal layers is not supported.

By default, the metal layers from M2 to the maximum metal layer specified earlier in the floorplan planner are allowed for pin placement. If the maximum metal layer has not been specified, the maximum available metal layer

specified in the technology file is used as the default. If the maximum layer specified is beyond the maximum metal layer for the current design then the latter figure is used.

-pin_spacing *pin_spacing_number*

Specifies the number of wire tracks between adjacent pins or between a pin and a preroute wire that cuts across a soft macro edge in the normal direction. Note that created pins are always snapped to wire tracks. The default pin-to-pin spacing is one wire track.

-hard_constraints {off | spacing | location | layer}

Specifies whether the pin spacing constraints, location constraints, and metal layer constraints are hard or soft constraints.

You can specify one or more of the following values:

- **off** (default)

The pin-to-pin spacing constraint specified by the **-pin_spacing** option is treated as a soft constraint.

- **spacing**

The pin-to-pin spacing constraint specified by the **-pin_spacing** option is treated as a hard constraint. An error occurs during pin assignment if there are insufficient pin slots to honor the constraint.

- **location**

The pin location constraint specified by the **read_io_constraints** or **set_pin_physical_constraints** command is treated as a hard constraint. Pins are created at the exact locations and pin assignment gives warnings if there are pin spacing violations.

- **layer**

The pin layer constraint specified by the **read_io_constraints** or **fset_pin_physical_constraints** command is treated as a hard constraint. Pins are created at the layer based on the physical constraints and pin placement gives warnings if the specified pin layer is not within the allowed layer constraints.

The pin layer constraint can be treated as a hard constraint only when the pin location constraint is also treated as a hard constraint. See the EXAMPLES section for an example of setting hard pin layer constraints.

By default, the constraints are soft constraints.

-pin_preroute_spacing *preroute_spacing_number*

Specifies the number of wire tracks between pins and preroutes.

To allow enough space for routing, no pins are created on the section of a soft macro edge that is parallel to a preroute if that edge is closer to the preroute than to the specified number of wire tracks.

IMPORTANT: Please note that this spacing pertains to the distance between a macro edge and an edge of a preroute that runs parallel to the macro edge. When a preroute runs into a soft macro across a macro edge in the normal perpendicular direction, the distance between soft macro pins on that macro edge and the preroute is dictated by the **-pin_spacing** option.

The default is three wire tracks.

-no_stacking *stacking_allowed* | pg_pins_only | signal_pins_only | all

Specifies how to handle pin overlaps across layers. The default method is

`stacking_allowed`.

The supported methods are described below.

- **`stacking_allowed`** (default)

Signal and power and ground pins can be stacked.

- **`pg_pins_only`**

Power and ground pins cannot be stacked. Signals pins can be stacked.

- **`signal_pins_only`**

Signal pins cannot be stacked. Power and ground pins cannot be stacked.

- **`all`**

Signal and power and ground pins cannot be stacked.

Note: The **`set_fp_pin_constraints`** command operates only on signal pins.

`-corner_keepout_num_wiretracks wiretracks_number`

Specifies the distance in wire tracks from the corners of soft macros where pin placement should begin.

Pin assignment and pin cutting multiplies the specified argument by the maximum metal layer pitch (the maximum wire track distance for metal layers from minimum to maximum) and uses the resulting distance as the corner spacing. For example, if the minimum layer is metal3 and the maximum layer is metal6 and the metal6 pitch is the largest, the corner spacing is calculated as the metal6 pitch multiplied by the number of wire tracks from the corners of soft macros.

This option can not be used together with the **`-corner_keepout_percent_side`** option. If neither option is specified, the default distance is five wire tracks.

`-corner_keepout_percent_side keepout_percentage`

Specifies the distance as a percentage of edge length from the corners of soft macros where pin placement should begin.

This option is similar to the **`-corner_keepout_num_wiretracks`** option, except that the corner keepout spacing is specified as a percentage of the edge length.

This option can not be used together with the **`-corner_keepout_num_wiretracks`** option. If neither option is specified, the default distance is five wire tracks.

`-exclude_sides side_numbers`

Specifies the soft macro edges on which pins cannot be placed. The argument is a string consisting of a number or a set of numbers separated by commas.

Each number corresponds to a macro or plan group edge. The leftmost edge is numbered 1 (one). Other edges are numbered according to their order of traversal in the clockwise direction starting from edge 1. If there are multiple leftmost edges then the edge 1 is the lowest leftmost edge. For example, to exclude sides 2, 4, and 6, enter

"2,4,6"

The default is 0 (no sides are excluded).

`-allow_feedthroughs off | on`

Specifies whether feedthrough ports can be created.

By default, this option is **`off`** (no feedthrough ports are created).

If set to **`on`**, pin assignment and cutting creates at least two feedthrough

ports in the child cell. Each top-level net for which a feedthrough port is created is split into a set of new top-level nets and child-level nets (if feedthrough nets were created for the child net). Directions are assigned for the newly created feedthrough ports. Because new ports are created in the soft macros, the netlist is modified as well.

-exclude_network

Propagates feedthrough exclusion nets through combinational circuits.

By default, feedthrough exclusions are not propagated through combinational circuits.

When used, all nets connected by combinational logic to nets specified as feedthrough exclusions are also excluded. For example, if nets A and B are excluded from feedthroughs due to the use of one or more of -
-exclude_clock_feedthroughs, **-exclude_hfn_feedthroughs**, -
-exclude_feedthroughs, and **-exclude_scan_chain_net_feedthroughs**, all nets connected to A and B via combinational logic are similarly excluded from feedthrough creation.

This option is not additive in the sense that **set_fp_pin_constraints** does not have any memory of the use of this option in previous invocations.

This option is ignored unless it is used together with the -
allow_feedthroughs on option.

-exclude_clock_feedthroughs off | on

Specifies whether feedthrough port creation is excluded on clock nets.

By default, this option is **on** (clock nets are excluded).

This option is ignored unless it is used together with the -
allow_feedthroughs on option.

-exclude_scan_chain_net_feedthroughs off | on

Specifies whether feedthrough port creation is excluded on scan chain nets.

By default, this option is **on** (scan chain nets are excluded).

This option is ignored unless it is used together with the -
allow_feedthroughs on option.

-exclude_hfn_feedthroughs hfn_number

Excludes feedthrough port creation on nets with a fanout greater than the specified number.

By default, feedthrough port creation is allowed on all nets (fanout limit of -1).

This option is ignored unless it is used together with the -
allow_feedthroughs on option.

-exclude_feedthroughs nets

Excludes feedthrough port creation on the specified nets.

The effect of this option is not cumulative. A subsequent call to **set_fp_pin_constraints** that uses this option overrides the previous setting.

For example, after the following successive calls to **set_fp_pin_constraints**, feedthrough exclusion applies only to net B:

**set_fp_pin_constraints -allow_feedthroughs on **

-exclude_feedthroughs [get_nets A]

**set_fp_pin_constraints -allow_feedthroughs on **

-exclude_feedthroughs [get_nets B]

Note that subsequent calls to **set_fp_pin_constraints** that do not use the -
exclude_feedthroughs option do not change the existing setting.

To remove all nets previously specified with this option from feedthrough

exclusion, use this option with an empty collection as argument, -
exclude_feedthroughs {}.

This option is ignored unless it is used together with the -
allow_feedthroughs on option.

-incremental off | on

Specifies whether the pin assignment or pin cutting is incremental. By default, this option is **off**.

In the top-down pin assignment flow, if the value is **on**, the **place_fp_pins** command retains the existing soft macro pins. If the value is **off**, it deletes and reassigns the soft macro pins.

In the block-level pin assignment flow, if the value is **on**, the **place_fp_pins** command retains the existing terminals. If the value is **off**, it deletes and reassigns the terminals.

In the pin cutting flow, if the value is **on**, the previously finalized routes generated by the **analyze_fp_routing -finalize_pins_feedthroughs plan_groups** command are retained. If the value is **off**, the previously finalized routings are abandoned.

-nets nets

Specifies the nets for which to perform pin assignment.

By default, pin assignment is performed on all nets.

This option and the **-exclude_nets** option are mutually exclusive; specify only one.

NOTE: Currently this option is not incremental. A subsequent call to the **set_fp_pin_constraints** command disables this option and nullifies the previously supplied arguments. Hence, a call to set_fp_pin_constraints using this option should be the last call before pin placement or routing.

-exclude_nets nets

Specifies the nets for which pin assignment is not performed.

By default, pin assignment is performed on all nets.

This option and the **-nets** option are mutually exclusive; specify only one.

NOTE: Currently this option is not incremental. A subsequent call to the **set_fp_pin_constraints** command disables this option and nullifies the previously supplied arguments. Hence, a call to set_fp_pin_constraints using this option should be the last call before pin placement or routing.

-keep_buses_together off | on

Specifies whether the pins associated with bus bits are grouped together.

By default, the bus bits are not kept together (**-keep_buses_together off**).

-bus_ordering lsb_to_msb | msb_to_lsb | scrambled | consistent_wirelengths

Specifies the method used for ordering the bus bits. This option is valid only if the **-keep_buses_together** option is enabled.

The supported methods are described below.

- **lsb_to_msb** (default)

Pins are ordered from the least significant bit to the most significant bit, and from left to right on a horizontal edge and bottom to top on a vertical edge. For example, a[0], a[1], a[2], ... a[31] for the 32-bit bus "a".

- **msb_to_lsb**

Pins are ordered from the most significant bit to the least significant bit, and from left to right on a horizontal edge and bottom to top on a vertical

edge. For example, a[31], a[30],

- **scrambled**

Bits are first sorted in increasing order and then ordered using the skip count specified in the **-scramble_skip** option. For example, using a skip count of 1, the bits are ordered as

a[0], a[2], a[4],... a[30], a[1], a[3],
a[5], ... a[31]

Using a skip count of 2, the bits are ordered as

a[0], a[3], a[6], ... a[1], a[4], a[7],
... a[2], a[5], a[8],...

- **consistent_wirelengths**

Bits are ordered to equalize the wire lengths of the bus bits between soft macros. This is not a valid selection if the **-block_level** option is used for block-level pin assignment.

-scramble_skip skip_number

Specifies the skip count for scrambled bus bit ordering. This option is valid only if the **-bus_ordering** option is enabled using the scrambled method. The default skip count is 1.

-use_physical_constraints off | on

Specifies whether pin assignment should honor pin physical constraints set by the **set_pin_physical_constraints** command or read with the **read_io_constraints** command.

By default, pin assignment does not use physical constraints (**-use_physical_constraints off**).

If this option is set to **on**, preexisting physical constraints loaded with the **set_pin_physical_constraints** or **read_io_constraints** command are enforced.

-block_level

Applies constraints on block-level pins instead of soft macro pins.

blocks

Specifies the soft macros and plan groups to which the specified constraints apply.

By default, the specified constraints apply to all soft macros and plan groups.

DESCRIPTION

This command allows you to set pin assignment constraints to be honored during pin cutting and pin assignment (see the man pages for **assign_fp_pins** and **commit_fp_plan_groups**). The pin assignment constraints are saved in the Milkyway database.

The **set_fp_pin_constraints** command is additive. The constraint values set in previous calls are retained unless they are explicitly overridden by subsequent calls.

Use the **remove_fp_pin_constraints** command to reset all constraint values to their defaults.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command allows feedthrough pins to be created on soft macros A, B, and C. All other pin constraints for A, B, and C are retained. If pin constraints were not previously defined for these soft macros, default values are used for all other pin constraints. If any of A, B, or C are plan groups, the pin constraints are migrated to their corresponding soft macros after you run the **commit_fp_plan_groups** command.

```
prompt> set_fp_pin_constraints -allow_feedthroughs on \
      [get_cells A B C]
```

The following command restricts pins to be on layers M2 through M5 on all soft macros and plan groups.

```
prompt> set_fp_pin_constraints -allowed_layers {M2 M3 M4 M5}
```

The following commands allow block-level pins to be created at the exact location and layers based on the preexisting physical constraints loaded with the **set_pin_physical_constraints** or **read_io_constraints** command.

```
prompt> set_fp_pin_constraints -block_level \
      -use_physical_constraints on \
      -hard_constraints {layer location}
```

`commit_fp_plan_groups(2)`
`read_io_constraints(2)`
`set_pin_physical_constraints(2)`
`analyze_fp_routing(2)`

set_fp_placement_strategy

Sets parameters for controlling the command **create_fp_placement**.

SYNTAX

```
status set_fp_placement_strategy
[-default]
[-macro_orientation automatic | all | N]
[-auto_grouping none | user_only | low | high]
[-macro_setup_only on | off]
[-macros_on_edge on | off | auto]
[-snap_macros_to_user_grid on | off]
[-sliver_size distance]
[-fix_macros none | soft_macros_only | all]
[-congestion_effort low | high]
[-IO_net_weight float]
[-plan_group_interface_net_weight float]
[-voltage_area_interface_net_weight float]
[-voltage_area_net_weight_LS_only on | off]
[-legalizer_effort low | high]
[-spread_spare_cells on | off]
[-virtual_IP0 on | off]
[-pin_routing_aware on | off]
```

ARGUMENTS

```
-default
    Set all the default parameter values.

-macro_orientation automatic | all | N
    Controls how macro orientations will be determined. Automatic means that the tool will analyze the macro's reference library cell and determine a good orientation for each reference library cell based on the pins on the reference cell. All means macros can rotate to any legal orientation during placement. N means all macros will be in a LEF/DEF N (ie PDEF 0) orientation or a flipped version of N (ie one of N, S, FN, FS). Default is automatic. Note that any reference library or user set orientation constraint will override this parameter.

-auto_grouping none | user_only | low | high
    Controls the amount of array packing done. None means that no macro arrays will be generated. User_only means that only user defined macro arrays will be generated. Low is the default value and means that automatic macro arrays will be generated from small macros only. High means automatic macro arrays will be generated from all macros.

-macro_setup_only on | off
    Causes the placer to only create the macro arrays outside the chip and place macros according to their relative location constraints, and then stop without doing placement. User can then manually place the macro arrays if desired. Default is off.
```

-macros_on_edge on | off | auto
Determines whether macros are placed along edges of chip or plan group. If on, all macros are placed along the edge; if auto, the tool will automatically decide which macros are to be placed along the edge. In a hierarchical design, it is recommended to set this to off until plan groups are shaped/placed inside the chip core. This is to avoid biasing the plan group locations to be on the edge. Default is auto.

-snap_macros_to_user_grid on | off
Snaps the lower left corner of macro's bounding box onto a user defined grid. A user grid is created by the command `set_user_grid`, see `set_user_grid` man page for details. Default is off.

-sliver_size *distance*
Controls the minimum channel size between macros which allows standard cells to be placed within it. The value is in microns. For example, if sliver_size is 10, then a channel of height 9 would not have any standard cells inside it. Default value is 0. Allowed range is >= 0.

-fix_macros none | soft_macros_only | all
Controls whether macros should be temporarily fixed for **create_fp_placement**. None means all macros are allowed to move during placement. Soft_macros_only means all soft macros will not move during placement. All means all macros will not move during placement. Default is none. This control does not change the "fixed" attribute on macros.

-congestion_effort low | high
Controls effort level of congestion driven placement. If the effort level is high, global routing procedure will be called and the routing congestion map will be used in the congestion driven placement. Default value is low.

-IO_net_weight *float*
Controls the net weight on nets connected to IOs. Default value is 1.0. Allowed range is between 0.0 and 10.0.

-plan_group_interface_net_weight *float*
Controls the net weight on interface nets of plan groups. Default value is 1.0. Allowed range is between 0.0 and 10.0.

-voltage_area_interface_net_weight *float*
Controls the net weight on interface nets of voltage areas. Default value is 1.0. Allowed range is between 0.0 and 10.0.

-voltage_area_net_weight_LS_only on | off
Controls the net weight set by the option `-voltage_area_interface_net_weight` to apply to nets connected to level shifter or isolation cells only. Default is off.

-legalizer_effort low | high
Controls the effort level of legalizer. Use low if legalizer is running too long. Default is high.

-spread_spare_cells on | off
Spread cells which have no net connectivity across the design. Default is on.

```
-virtual_IPO on | off
    Controls whether to use virtual IPO during timing driven placement. Default
    is off.

-pin_routing_aware on | off
    Determines whether macro placement should consider reserving the area for
    routing resources to pins of a block or plan group. Default is off.
```

DESCRIPTION

This command sets parameters for controlling the design planning commands **create_fp_placement** and **legalize_fp_placement**. These settings are not applicable to other ICC placement commands or other parts of the flow. These settings are not persistent in the database.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLE

The following examples sets the sliver size to 10.5 microns.

```
prompt> set_fp_placement_strategy -sliver_size 10.5
INFO: Setting sliver_size = 10.50
```

SEE ALSO

```
report_fp_placement_strategy(2)
create_fp_placement(2)
set_user_grid(2)
```

set_fp_power_pad_constraints

Defines the power pad synthesis constraints.

SYNTAX

```
status set_fp_power_pad_constraints
[-honor_existing_pads | -honor_even_space]
[-target_pad_current current]
[-maximum_number_of_pads number]
[-save_file file_name]
```

Data Types

<i>current</i>	float
<i>number</i>	integer
<i>file_name</i>	string

ARGUMENTS

-honor_existing_pads

Honors all existing power and ground pads during pad synthesis. By default, the tool ignores existing power and ground pads during pad synthesis. However, virtual pads that you create are always honored during pad synthesis. This option and the **-honor_existing_space** option are mutually exclusive; you can specify only one.

-honor_even_space

Honors existing pads that have an even amount of space between them during pad synthesis. By default, the tool ignores existing power and ground pads during pad synthesis. However, virtual pads that you create are always honored during pad synthesis.

-target_pad_current *current*

Specifies the target pad current value (in mA). Power pad synthesis adds power pads and attempts to place them such that both the maximum pad current (and voltage drop) and the maximum number of power pads are simultaneously satisfied. There is no default value.

-maximum_number_of_pads *number*

Specifies the maximum number of pads to be considered during pad synthesis. The default value is 40.

-save_file *file_name*

Specifies the name of the virtual pad file that is generated during pad synthesis. This virtual pad file can be read in by the **fp_create_virtual_pad -load_file** command. The default file name is default.vpad.

DESCRIPTION

Power pad synthesis determines the number of power pads and their locations based on the chip area and a target IR drop for boundary I/O designs. It can solve IR drop problems without modifying the existing design's power structure. Power pad synthesis can be performed simultaneously with power network synthesis.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to set power pad synthesis constraints that honor existing power and ground pads in the design, limit the pad current to be under 60mA and save the constraints to foo.vpad.

```
prompt> set_fp_power_pad_constraints\
-honor_existing_pads -target_pad_current 60.0\
-save_file foo.vpad
```

SEE ALSO

set_fp_rail_constraints

Defines power network synthesis (PNS) constraints, including layer constraints, power ring and strap constraints, and global constraints.

SYNTAX

```
status set_fp_rail_constraints
[-add_layer
 | -remove_layer
 | -remove_all_layers
 | -set_ring

<i>distance</i>	float
<i>nets</i>	collection or list

ARGUMENTS

```
[-add_layer | -remove_layer | -remove_all_layers | -set_ring | -skip_ring | -
```

set_fp_rail_constraints

2326

set_global

Specifies the type of constraint being set. These options are mutually exclusive; specify only one.

Specify **-add_layer** to add power strap layer constraints.
or
Specify **-remove_layer** to remove power strap layer constraints.
or
Specify **-remove_all_layers** to remove all the power strap layer constraints.
or
Specify **-set_ring** to add power ring constraints.
or
Specify **-skip_ring** to disable power ring generation.
or
Specify **-set_global** to add global constraints.

-layer layer

Specifies the layer on which to create the power grid. This option is valid only when you also specify the **-add_layer** or **-remove_layer** option.

-direction vertical | horizontal

Specify the direction for the power and ground wires.
This option is valid only when you also specify the **-add_layer** option.

By default, the preferred routing direction of the specified layer is used.

-max_strap number

Controls the power strap density by setting the maximum number of straps.
This option is valid only when you also specify the **-add_layer** option.
The default is 128. This option and **-min_strap** option are mutually exclusive to **-max_pitch** and **-min_pitch** options.

-min_strap number

Controls the power strap density by setting the minimum number of straps.
This option is valid only when you also specify the **-add_layer** option.
The default is 16. This option and **-max_strap** option are mutually exclusive to **-max_pitch** and **-min_pitch** options.

-max_pitch distance

Specifies the maximum pitch (in microns).
This option is valid only when you also specify the **-add_layer** option.
This option and **-min_pitch** option are mutually exclusive to **-max_strap** and **-min_strap** options.

-min_pitch distance

Specifies the minimum pitch (in microns).

This option is valid only when you also specify the **-add_layer** option.
This option and **-max_pitch** option are mutually
exclusive to **-max_strap** and **-min_strap** options.

-max_width *distance*

Specifies the maximum width of the power wires (in microns).
This option is valid only when you also specify the **-add_layer** option.

If you do not specify this option, the tool uses the maximum
width that is defined in the technology file.

-min_width *distance*

Specifies the minimum width of the power wires (in microns).
This option is valid only when you also specify the **-add_layer** option.

If you do not specify this option, the tool uses the minimum
width that is defined in the technology file.

-spacing *distance* | **minimum** | **interleaving**

Constrains the spacing between the power and ground wires, so that signals
may
be able to route between the P/
G networks. User can choose minimum spacing(**minimum**)
or interleaving (**interleaving**), or explicitly specify the *distance*
in the unit of microns. The default is **minimum**.
This option is valid only when you also specify the **-add_layer** option.

-offset *distance*

Specifies the offset from the I/
O pads to the nearest power straps (in microns).
This option is valid only when you also specify the **-add_layer** option.

-nets *nets*

Specifies the nets that make up the core rings. To generate multiple
core rings, specify multiple nets. The first net is be the outermost ring.
This option is valid only when you also specify the **-set_ring** option.

-horizontal_ring_layer *layer*

Specifies the horizontal metal layers for the power ring.
This option is valid only when you also specify the **-set_ring** option.

The default horizontal layer is the highest horizontal layer in
the database.

-vertical_ring_layer *layer*

Specifies the vertical metal layers for the power ring.
This option is valid only when you also specify the **-set_ring** option.

The default vertical layer is the highest vertical layer in the database.

-ring_width *distance*

Specifies the width of the power rings (in microns).

This option is valid only when you also specify the **-set_ring** option.

If this option is not set, by default the tool will automatically determine the ring width to meet the IR drop requirements.

You cannot specify this option together with the **-ring_max_width** or **-ring_min_width** option.

-ring_max_width *distance*

Specifies the maximum allowable core ring width (in microns).

This option is valid only when you also specify the **-set_ring** option.

If you specify this option, you cannot specify the **-ring_width** option.

-ring_min_width *distance*

Specifies the minimum allowable core ring width (in microns).

This option is valid only when you also specify the **-set_ring** option.

If you specify this option, you cannot specify the **-ring_width** option.

-ring_spacing *distance*

Specifies the spacing between the core rings (in microns).

This option is valid only when you also specify the **-set_ring** option.

-ring_offset *distance*

Specifies the offset from the I/O pads to the power rings (in microns).

This option is valid only when you also specify the **-set_ring** option.

-extend_strap *core_ring | boundary | pad_ring*

If you choose to generate a power plan without a core ring, you must tell PNS how to connect (extend) the generated horizontal and vertical power straps.

This option is valid only when you also specify the **-set_ring** or **-skip_ring** option.

There are three options:

core_ring (default)

PNS extends the power straps to the existing core ring.

boundary

PNS extends the power straps to the top-level cell boundary and creates power pins.

pad_ring
 PNS extends the power straps to an existing pad ring.

-keep_floating_segments
 Instructs PNS to keep dangling wires cut by hard macros or blockages. This option is valid only when you also specify the **-set_global** option. By default, dangling wires cut are removed.

-no_stack_via
 Prevents PNS from using stack via (vias are dropped only on adjacent layers). This option is valid only when you also specify the **-set_global** option. By default, PNS uses stack vias.

-no_same_width_sizing
 Allows PNS to create wires that have different widths for power and ground nets. This option is valid only when you also specify the **-set_global** option. By default, PNS creates wires with the same width for power and ground nets.

-optimize_tracks
 PNS sizes wires so that it leaves enough space for the power and ground wire's adjacent tracks to be used for signal routes.
 By default, no sizing is performed on P/G wires.
 This option is valid only when you also specify the **-set_global** option.

-keep_ring_outside_core
 PNS creates the core ring outside of the core area. This option is valid only when you also specify the **-set_global** option.

-no_routing_over_hard_macros
 Prevents PNS from routing over hard macros. This option is valid only when you also specify the **-set_global** option.

-no_routing_over_plan_groups
 Prevents PNS from routing over plan groups, despite the absence of blockages.
 This option is valid only when you also specify the **-set_global** option.

-no_routing_over_soft_macros
 Prevents PNS from routing over soft macros, despite the absence of blockages.
 This option is valid only when you also specify the **-set_global** option.

-ignore_blockages
 Allows PNS to create power wires despite hard macro blockages. This option is valid only when you also specify the **-set_global** option.
 By default, PNS honors hard macro blockages to create a DRC-clean power plan.

DESCRIPTION

This command sets the power network synthesis (PNS) constraints for power planning, including power strap layer constraints, power ring constraints, and global constraints. Multiple core rings and sandwich core rings can also be generated.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to set the power network synthesis layer constraints. The horizontal layer is METAL5 with a maximum of 20 straps and a minimum of 5 straps; the vertical layer is METAL6 with a maximum of 40 straps and a minimum of 8 straps.

```
prompt> set_fp_rail_constraints \
-add_layer -layer METAL5 \
-direction horizontal \
-max_strap 20 \
-min_strap 5 \

prompt> set_fp_rail_constraints \
-add_layer -layer METAL6 \
-direction vertical \
-max_strap 40 \
-min_strap 8 \
```

SEE ALSO

`report_fp_rail_constraints(2)`
`synthesize_fp_rail(2)`

set_fp_rail_region_constraints

Defines the region where power plan synthesis creates a rectilinear power mesh.

SYNTAX

```
status_value set_fp_rail_region_constraints
[-voltage_area voltage_area
 | -polygon
-load_file file_name
 | -remove]
[-save_file file_name]
```

Data Types

<i>voltage_area</i>	collection or list of one object
<i>polygon_area</i>	list
<i>file_name</i>	string

ARGUMENTS

-voltage_area *voltage_area*

Defines the PNS region based on the specified voltage area. You can specify only a single voltage area.

By default, the command creates a region based on the DEFAULT_VA voltage area. The DEFAULT_VA voltage area includes the whole core area excluding existing voltage areas.

This option and the **-polygon**, **-load_file**, and **-remove** options are mutually exclusive; you must specify only one.

-polygon {*polygon_area*}

Defines a rectilinear PNS region based on the user specified polygon area. A polygon is identified by specifying the coordinates of all its points. The format is {{x1 y1} {x2 y2} ...}.

This option and the **-voltage_area**, **-load_file**, and **-remove** options are mutually exclusive; you must specify only one.

-load_file *file_name*

Defines a rail region by loading the specified region definition file.

This option and the **-voltage_area**, **-polygon**, and **-remove** options are mutually exclusive; you must specify only one.

-remove

Deletes the currently defined rail region. Note that after commit, all defined rail regions are automatically deleted.

This option and the **-voltage_area**, **-polygon**, and **-load_file** options are mutually exclusive; you must specify only one.

-save_file *file_name*

Saves the defined rail region to the specified file.

This option is optional. The default file name is default.region.

DESCRIPTION

Defines the region where power plan synthesis creates a rectilinear power mesh.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example defines a region for power network synthesis with the coordinates {1200.00 952.00 1200.00 650.00 1400.00 650.00 1400.00 952.00} and saves the definition to foo.region.

```
prompt> set_fp_rail_region_constraints \
    -polygon {1200 952 1200 650 1400 650 1400 952} \
    -save_file foo.region
```

ARGUMENTS

-reset
Reset all the PNS/PNA strategy.

set_fp_rail_strategy

2334

```

-use_lm_view true | false
    Uses the LM view for power calculations. The default value is false.

-use_tluplus true | false
    Specifies for power network synthesis (PNS) and power network analysis (PNA)
    to use the TLU+ model. PNA and PNS use the TLU+ model when either of the
    following conditions are met:
        • This option is set to true.
    Resistance values in technology files are not defined.
    The default value is false.

-pna_ultra_solver true | false
    Enables PNA to use the ultra-solver, which uses less memory but more CPU time.
    The default value is false.

-virtual_pad_wire_width virt_wire_width
    Defines the width of the virtual wires used to connect the virtual pads and
    their neighboring wires. By default, the PNS/PNA virtual pad uses the closest
    wire width for a virtual connection.

-define_pad_connection connection_config_file_name
    Enables PNA to make virtual connections from power and ground pads to power
    and ground wires based on a pre-defined connection configuration specified
    by the connection_config_file_name. The file includes pad master/instance
    name, connected pin layers, and routing layers. The format of the
    configuration file is as follows:

    Instance|Master <name>
        Route Pins layer <layer_number> | all
            Primary Routing Layer Preferred low | high
            Or
            Primary Routing Layer Pin
            Or
            Primary Routing Layer Specified Horizontal layer_number
            Primary Routing Layer Specified Vertical layer_number
            I. Pad Instance/Master name: Specifies the instance or master name of pads.
            II. Connected pin layers: Connects only pins on All layers or the specified
                layer.
            III. Primary Routing Layer: Specifies how to pick the layer on which to route.
                Valid keywords are: preferred | pin | specified.
            Use preferred to route on preferred metal layers. You can further refine
            routing by using the low or high keyword, where high routes on the next
            available higher preferred layer. If a higher preferred layer is not
            available, use low to route on an available lower preferred layer. Use pin
            to route on the same layer on which the pins are located. Use specified to
            route on layers. Use the keywords horizontal layer_number or vertical
            layer_number to define horizontal and vertical routing layers. See an example
            of using the -define_pad_connection option in the EXAMPLE section.

-pad_resistance_file pad_resistance_file_name
    Specifies the file from which to read pad resistance. This file is used to
    add extra resistance for power and ground pads.

```

```
-pns_skip_ir true | false
    Causes PNS to skip IR drop simulation by specifying true. By default, PNS
    always performs IR drop simulation before committing the results. When this
    option is set to true, the number and width of the specified straps for all
    defined layers are fixed (maximum is equal to minimum). The default value is
    false.
```

```
-honor_macro_strap_config configuration_file
    Enables PNS to accept user-defined power and ground configurations with
    layer, direction, width, pitch, and offset on the specified hard macros or
    rectangle regions. PNS synthesizes the remaining area based on your
    constraints.
```

The format of the configuration file is as follows:

```
<region_type> <name or polygon>
Layer <layer_name> Direction <direction> Width <width>
Pitch <pitch> Offset <offset>
User one of the keywords: Instance or Master or Region to specify the region
type. For Instance or Master, specify its name next; for user-defined region,
specify the region polygon. This must be specified in a separate line from
below. layer_name can be either layer name or mask name; direction can be one
of the keywords: Horizontal or Vertical; width, pitch and offset are floating
numbers. User can specify multiple layers for one region. See the examples
in the EXAMPLE section for more detailed usage of this strategy.
```

```
-pns_hor_relative_offset {h_layer h_rel_offset}
    Specifies the relative offsets from the top-most horizontal layer to the
    specified layer so that PNS synthesizes nonoverlapping straps with the same
    directional layers. This option is used when there are more than two layers
    of power and ground straps.
    This option has two arguments, so you must enclose them in curly brackets {}.
    The first argument, h_layer, is the layer name. The second argument,
    h_rel_offset, is the offset (in microns) from the top-most layer to the
    specified layer.
    If the offset is a positive value, the straps for the specified layer are
    above the corresponding top-layer straps. If the offset is a negative value,
    the straps for the specified layer are below the corresponding top-layer
    straps. You can reset this strategy by specifying an empty string. By default,
    PNS generates overlapping straps on different layers with the same direction.
```

```
-pns_ver_relative_offset {v_layer v_rel_offset}
    Specifies the relative offsets from the top-most vertical layer to the
    specified layer so that PNS synthesizes nonoverlapping straps with the same
    directional layers. This option is used when there are more than two layers
    of power and ground straps.
    This option has two arguments, so you must enclose them in curly brackets {}.
    The first argument, v_layer, is the layer name. The second argument,
    v_rel_offset, is the offset (in microns) from the top-most layer to the
    specified layer.
    If the offset is a positive value, the straps for the specified layer are to
    the right of the corresponding top-layer straps. If the offset is a negative
    value, the straps for the specified layer are to the left of the corresponding
    top-layer straps. You can reset this strategy by specifying an empty string.
    By default, PNS generates overlapping straps on different layers with the
    same direction.
```

-pns_ignore_via_cut_to_edge true | false
 Causes the synthesized power and ground wires to ignore the via's cut to edge spacing when you set this option to the **true** value. This strategy enables PNS to use smaller spacing values, (defined in technology file), but it might result in a design rule checking (DRC) violation. The default is **false**.

-pns_ignore_soft_macro_blockage true | false
 Ignores soft macro blockages when you set this option to the **true** value. The default is **false**.

-pns_clip_top_boundaries true | false
 Causes PNS to turn on the "clip at top-cell boundaries" option in the preroute engine when committing power networks when you set this option to the **true** value. The default is **false**.

-cut_plangroup_edge_layers layers
 Specifies the layer on which synthesized straps are removed if they overlap with plangroup edges. Users can use the keyword "all" to cut synthesized straps that overlap plangroup edges on all layers. By default, this strategy is off.

-pna_via_cut_row_column number
 Breaks a large square or a rectangular via array into smaller square via arrays based on the value specified by *number*.

-honor_macro_route_constraints routing_constraints_file_name
 Specifies routing constraints for macros in an input file that identifies the constraints. The *routing_constraints_file_name* input file should define the macro type (master or instance), macro name (master name or instance name), net name (the net to block), and layer name (the layer to block, or use keyword **all** to block routing on all metal layers). By default, the command uses no routing constraints.

-align_strap_with_top_pin true | false
 If this strategy is specified, PNS will align power and ground straps with power and ground pins on block boundary. The alignment strap layer will be the layer of the pin and the strap width will be the pin width. In addition, PNS will also generate other non-aligned straps to satisfy the target IR drop. However, if user does not want PNS to generate other straps except for the aligned straps, user can set the Tcl variable **pns_pin_alignment_strap_only** to **true**.
 This strategy is especially useful in block-level PNS. By default this strategy is **false**.

-align_strap_with_mtcmos_cells alignment_constraints_file_name
 Causes PNS to align the power straps with MT莫斯 cells and connect straps to the corresponding pins in the MT莫斯 cells based on the constraint file specified by the *alignment_constraints_file_name* argument. This strategy is used to configure primary power straps in MVDD PNS for power-gated voltage areas.
 You can specify the following information in the configuration file, one net per line:
net_name direction width layer VA_name
 where

- *net_name* is the name of the primary power net to align.
 - *direction* is the alignment direction, the value of which can be one of **horizontal**, **vertical**, or **ring**.
 - *width* is the width of aligned primary power straps
 - *layer* is the layer name of aligned primary power straps (in the ring MTMOS placement style, *layer* should include both the horizontal and vertical ring layer names).
 - *VA_name* specifies which voltage area this strategy is applied to.
- The following example shows how to specify a configuration file. In this example, there are two voltage areas: VA1 and VA2. Both voltage areas are power-down voltage areas. VA1 uses the VDD1 primary power net and VA2 uses the VDD2 primary power net. VA1 uses array-style MTMOS placement and VA2 uses ring-style MTMOS placement.

The content of file `example.align` should look like the following:

```
VDD1 vertical 1.5 METAL6      VA1
VDD2 ring     1.0 METAL5,METAL6  VA2
```

Note that, for the *width* and *layer* fields, if you want power network synthesis to use the default value, you can use the **default** keyword to specify this, as shown in the following example:

```
VDD1 vertical default METAL6 VA1
```

You can reset this strategy by using an empty file name. By default, this strategy is set to NULL.

`-align_strap_with_bump_cells alignment_constraints_file_name`

If this strategy is specified, PNS will align power/ground straps with bump cells in the design based on the specification in the *alignment_constraints_file_name*.

The format of the constraint file is as follows:

```
net_name direction width layer
```

where

- *net_name* is the name of the power/ground net to align.
- *direction* is the alignment direction. The value is one of the string "horizontal" or "vertical".
- *width* is the width of aligned power/ground straps.
- *layer* is the layer name of aligned power/ground straps.

User can specify multiple lines in the file. The following example shows how to specify a configuration file. In this example, VDD and VSS are aligned with bump cells vertically on METAL6 with strap width 1.5 microns.

```
VDD vertical 1.5 METAL6
```

```
VSS vertical 1.5 METAL6
```

Note that, for the <width> and <layer> field, if user want PNS to use the default value, user could use keyword "default" to specify as follows:

```
VDD vertical default METAL6
```

You can reset this strategy by using an empty file name. By default this strategy is set to NULL.

`-align_strap_with_m1_rail true | false`

This option enables PNS to align synthesized power and ground straps in the lowest horizontal layer with the horizontal power and ground rails of standard cells to avoid horizontal power (or ground) straps overlapping with horizontal ground (or power) standard cell rails when you set this option to **true**. The default is **false**. Note that the fixed strap pitch, fixed strap offset and fixed power ground spacing might not be honored due to the alignment. Some straps might be discarded due to the limited number of

available standard cell rows. You can select "put core ring outside of core area" to avoid standard cell rails blocked by the core ring. This option is mutually exclusive with **put_strap_in_std_cell_row** option, i.e. only one of them could be set to true.

-put_strap_in_std_cell_row true | false

This option enables PNS to put synthesized power and ground straps in the lowest horizontal layer between standard cell power and ground rails inside standard cell rows when you set this option to **true**. The default is **false**. Therefore, straps may not be overlapped with standard cell rails even if they may be in the same logic net. Note that the fixed strap pitch, fixed strap offset and fixed power ground spacing might not be honored to avoid rail blockage. Some straps might be discarded due to the limited number of available standard cell rows. At most one strap may be laid within one standard cell row. You can select "put core ring outside of core area" to avoid standard cell rails blocked by the core ring. This option is mutually exclusive with **align_strap_with_m1_rail** option, i.e. only one of them could be set to true.

-commit_fast true | false

This strategy enables PNS to call the **create_power_straps** preroute command once for each layer when committing the synthesized power plan. The default is **false**, meaning that PNS calls **create_power_straps** once for each segment during the commit process.

-set_operating_temperature temperature

Specifies the operating temperature used for PNA and PNS. Since the metal resistance is dependent on operating temperature, PNA/PNS will use this user-specified operating temperature for IR drop analysis. The unit is degrees Celsius.

-create_hierarchical_pns_script true | false

This strategy enables power network synthesis at the top-level to create power network synthesis replay scripts for each plan group in the design such that after the plangroups are committed to soft macros, you can resynthesize power networks in each soft macro with the same power budget allocated from top-level and with a similar power network as pushed down from the top-level. The script considers voltage drops at the PG pins on the soft macro boundary during IR drop simulation in the block-level power network synthesis.

If this strategy is set to true, a subdirectory with the name *plangroup_name_PNS_script* is created for each plan group in the *pna_output* directory. In each *plangroup_name_PNS_script* subdirectory two files are generated:

plangroup_name.vin contains the voltage information for each pin on the plan group boundary.

plangroup_name_replay.tcl is the replay tcl file that can resynthesize the power network in the soft macro. Note that the *plangroup_name.vin* is called from this Tcl file.

By default, this strategy is set to false.

DESCRIPTION

This command sets parameters for power network synthesis (PNS) and power network

analysis (PNA). These settings are not persistent in Milkyway database.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following examples show how to define a pad connection file.

```
prompt> set_fp_rail_strategy\
-define_pad_connection "connection_file"
```

Example I: For pads with master name *KMVDDIOGS.FRAM*, pick pins with layer number 1, and use the same layers with pin to make connection.

```
<connection_file>:
Master KMVDDIOGS.FRAM
Route Pins Layer 1
Primary Routing Layer Pin
```

Example II: For pads with master name *KMVDDIOGS.FRAM*, pick pins with all layers, and use layer 1 as horizontal routing, and layer 11 vertical routing.

```
<connection_file>:
Master KMVDDIOGS.FRAM
Route Pins All
Primary Routing Layer Specified Horizontal 1
Primary Routing Layer Specified Vertical 11
```

Example III: For pads with master name *KMVDDIOGS*, pick pins with all layers, and use the same layers with pin to make connection. The connection rule is the same as the one in *preroute_instances*

```
<connection_file>:
Master KMVDDIOGS
Route Pins All
Primary Routing Layer Pin
```

The following example specifies the offset of 15 microns from the top edge of *metal3* power nets to the top edge of *metal5* power nets. Because the offset is a positive number, the *metal3* straps are above the corresponding *metal5* straps.

```
prompt> set_fp_rail_strategy\
-pns_hor_relative_offset "metal3 15"
```

The following example shows how to define customized P/G routing regions in PNS. In this example, P/G network on all the macros with master name *RAM* will be created vertically on *metal6* with width 4 microns, pitch 80 microns and offset 10 microns, horizontally on *metal5* with width 4 microns, pitch 60 and offset 10 microns.

```
prompt> set_fp_rail_strategy\
```

```

-honor_macro_strap_config "configuration_file1"
<configuration_file1>:
Master RAM
Layer metal6 Direction Vertical Width 4 Pitch 80 Offset 10
Layer metal5 Direction Horizontal Width 5 Pitch 60 Offset 10

```

The following example shows how to define customized P/G routing regions in PNS. In this example, P/G network in the defined region (7320 100 9110 1410) will be created vertically on *M8* with width 8.2 microns, pitch 60.5 microns and offset 6.2 microns, horizontally on *M7* with width 6 microns, pitch 60 and offset 6 microns.

```

prompt> set_fp_rail_strategy\
-honor_macro_strap_config "configuration_file2"
<configuration_file2>:
Region 7320 100 9110 1410
Layer M8 Direction Vertical Width 8.2 Pitch 60.5 Offset 6.2
Layer M7 Direction Horizontal Width 6 Pitch 60 Offset 6

```

The following example shows how to define a macro routing constraint in a file. In this example, *VDD* net will not route over all instances of cell master *BLENDER_1.CEL* on *METAL3*; *VDD* net will not route over all instances of cell master *BLENDER_2.CEL* on *METAL3* and *METAL4*; *VSS* net will not route over cell instance *I_ORCA_TOP/I_BLENDER_3* on all the metal layers.

```

prompt> set_fp_rail_strategy\
-honor_macro_route_constraints "route_constr_file"
<route_constr_file>:
master BLENDER_1.CEL VDD METAL3
master BLENDER_2.CEL VDD {METAL3,METAL4}
instance I_ORCA_TOP/I_BLENDER_3 VSS all

```

The following example shows how to specify MTCMOS alignment constraint in a file. In this example, *VDD* strap of width 2 microns on *METAL8* will be vertically aligned with all MTCMOS cells in voltage area *MULTIPLIER*, and *VSS* straps of width 1.5 microns on default metal layers will be horizontally aligned with instances of cell master *FOOTER.CEL* in all voltage areas. Here the default layer is the topmost metal layer on the specified direction.

```

prompt> set_fp_rail_strategy\
-align_strap_with_mtcmos_cells "align_constr_file"
<align_constr_file>:
VDD vertical 2 METAL8 MULTIPLIER
VSS horizontal 1.5 default all FOOTER.CEL

```

The following example shows how to specify bump cell alignment constraint in a file. In this example, *VDD* strap of width 2.0 microns on *METAL8* will be vertically aligned with *VDD* bump cells; *VSS* straps of width 2.0 microns on default metal layers will be horizontally aligned with *VSS* bump cells. The default layer is the topmost metal layer of the specified direction.

```
prompt> set_fp_rail_strategy\
```

```
-align_strap_with_bump_cells "align_constr_file"
<align_constr_file>:
VDD vertical 2.0 METAL8
VSS horizontal 2.0 default
```

SEE ALSO

`report_fp_rail_strategy(2)`

set_fp_rail_voltage_area_constraints

Defines power network synthesis (PNS) constraints for the specified voltage area. This command specifies four groups of PNS constraints: synthesis constraints, layer constraints, ring constraints, and global constraints. Note that these constraints cannot be specified together in command; they must be specified in separate commands.

SYNTAX

ARGUMENTS

-voltage_area *voltage_area*

Specifies the voltage area to which the constraints apply.
This is a required option.

-nets *pg_nets*

Specifies the power and ground (PG) nets to be synthesized in the specified voltage areas. For power-down voltage areas, specify the permanent and virtual PG net as "VDD_Permanent+VDD_Virtual". PNS synthesizes both nets together connected through power switch cells. If UPF is defined, PNS uses the primary power and ground net from the UPF.

This option belongs to the synthesis constraints group.

-voltage_supply *supply_voltage*

Specifies the supply voltage in the specified voltage areas. The *supply_voltage* value is in volts.

This option belongs to the synthesis constraints group and is required when specifying synthesis constraints.

-power_budget *power*

Specifies the power budget in the specified voltage areas. The *power* value is in milliwatts.

By default, power budgets are automatically assigned to each voltage area based on the total power budget specified by using the **synthesize_fp_rail** command.

This option belongs to the synthesis constraints group.

-target_voltage_drop *voltage*

Specifies the target voltage (IR) drop value in the specified voltage areas. The *voltage* value is in millivolts.

By default, the target IR drop value is 10 percent of the supply voltage in that voltage area.

This option belongs to the synthesis constraints group.

-power_switch power_switch_or_lib_cell
 Specifies the library cell to be used as the power switch in the specified voltage areas. In UPF mode, use the power switch cell name defined in the UPF. In non-UPF mode, use the library reference cell name.
 Use this option only for power switch synthesis. For more information, see the man page for the **synthesize_fp_rail** command.
 This option belongs to the synthesis constraints group.

-layer pg_layer
 Specifies the metal layers for the power and ground straps in the specified voltage areas.
 This option belongs to the layer constraints group and is required when specifying layer constraints.

-direction vertical | horizontal
 Specifies the direction of power and ground straps on the specified layers in the specified voltage areas.
 This option belongs to the layer constraints group and is required when specifying layer constraints.

-max_strap max_strap_number
 Specifies the maximum number of power and ground straps in the specified voltage areas.
 By default, the maximum number of straps is 128.
 You cannot use this option together with the **-max_pitch** or **-min_pitch** option.
 This option belongs to the layer constraints group.

-min_strap min_strap_number
 Specifies the minimum number of power and ground straps in the specified voltage areas.
 By default, the minimum number of straps is 16.
 You cannot use this option together with the **-max_pitch** or **-min_pitch** option.
 This option belongs to the layer constraints group.

-max_pitch max_pitch_distance
 Specifies the maximum pitch of the power and ground straps in the specified voltage areas. The *max_pitch_distance* value is in microns.
 You cannot use this option together with the **-max_strap** or **-min_strap** options.
 This option belongs to the layer constraints group.

-min_pitch min_pitch_distance
 Specifies the minimum pitch of the power and ground straps in the specified voltage areas. The *min_pitch_distance* value is in microns.
 You cannot use this option together with the **-max_strap** or **-min_strap** option.
 This option belongs to the layer constraints group.

-max_width max_width_distance
 Specifies the maximum width of the power and ground straps in the specified voltage areas. The *max_width_distance* value is in microns.
 By default, PNS uses the maximum width defined in the technology file.
 This option belongs to the layer constraints group.

-min_width min_width_distance
 Specifies the minimum width of the power and ground straps in the specified

voltage areas. The *min_width_distance* value is in microns. By default, PNS uses the minimum width defined in the technology file. This option belongs to the layer constraints group.

-spacing *minimum | interleaving | distance*
Specifies the spacing between power and ground straps in the specified voltage areas. Use **minimum** for minimum spacing, **interleaving** for interleaving, or *distance* for explicitly specified spacing in microns. By default, PNS uses minimum spacing.
This option belongs to the layer constraints group.

-offset *offset_distance*
Specifies the distance from the voltage area boundary to the left-most and bottom-most power strap. The *offset_distance* value is in microns. By default, PNS calculates the offset distance based on the number of straps, the strap pitch, and the strap width.
This option belongs to the layer constraints group.

-mtcmos_net_type *permanent | virtual*
Specifies the MTCMOS net type on the layer in power switch array synthesis. In power switch array synthesis, only one power net, either a permanent power net or a virtual power net, can be synthesized on one layer. The ground net, however, can be synthesized on any layer. This option is used only for power switch array synthesis (**synthesize_fp_rail -synthesize_power_switch_array**).
This option belongs to the layer constraints group.

-ring_nets *ring_nets*
Specifies the power and ground ring nets to be generated inside the specified voltage areas. To generate the core ring for each voltage area, you must first specify the ring nets in *DEFAULT_VA*, as shown in the EXAMPLES section. By default, the *ring_nets* are the same as the nets specified in the synthesis constraints for the voltage area.
This option belongs to the ring constraints group.

-skip_ring
Does not generate a power and ground ring in the voltage area.
The **-skip_ring** and **-ring_nets** options are mutually exclusive; use only one.
This option belongs to the ring constraints group.

-horizontal_ring_layer *h_ring_layer*
Specifies the horizontal metal layer for the power and ground ring in the voltage area. By default, PNS uses the highest horizontal metal layer.
This option belongs to the ring constraints group and must be specified with the **-ring_nets** option.

-vertical_ring_layer *v_ring_layer*
Specifies the vertical metal layer for the power and ground ring in the voltage area. By default, PNS uses the highest vertical metal layer.
This option belongs to the ring constraints group.

-ring_width *pg_ring_width*
Specifies the width of the power and ground ring in the voltage area. The *pg_ring_width* value is in microns.
By default, the ring width is twice the strap width in the voltage area, except for *DEFAULT_VA*. In *DEFAULT_VA*, the default ring width is ten times the

minimum width defined in the technology file for the specified ring metal layer.

The **-ring_width**, **-ring_max_width**, and **-ring_min_width** options are mutually exclusive; you can use only one.

This option belongs to the ring constraints group and must be specified with the **-ring_nets** option.

-ring_max_width *max_ring_width*

Specifies the maximum allowable ring width in the voltage area. The *max_ring_width* value is in microns.

The **-ring_width**, **-ring_max_width**, and **-ring_min_width** options are mutually exclusive; you can use only one.

This option belongs to the ring constraints group and must be specified with the **-ring_nets** option.

-ring_min_width *min_ring_width*

Specifies the minimum allowable ring width in the voltage area. The *min_ring_width* value is in microns.

The **-ring_width**, **-ring_max_width**, and **-ring_min_width** options are mutually exclusive; you can use only one.

This option belongs to the ring constraints group and must be specified with the **-ring_nets** option.

-ring_spacing *distance_between_rings*

Specifies the distance between the power and ground rings in the voltage area. The *distance_between_rings* value is in microns.

By default, PNS uses the minimum spacing from the technology file.

This option belongs to the ring constraints group and must be specified with the **-ring_nets** option.

-ring_offset *distance_to_boundary*

Specifies the distance from the voltage area boundary to the closest ring net. The *distance_to_boundary* value is in microns.

By default, the ring offset is 0.

This option belongs to the ring constraints group and must be specified with the **-ring_nets** option.

-extend_strap *voltage_area_ring | core_ring | boundary*

Specifies where to extend power and ground nets in the voltage area. This option takes one of the following keywords:

* **voltage_area_ring**

Extends the power and ground straps to the ring inside the voltage area.

* **core_ring**

Extends the power straps to the core ring in DEFAULT_VA.

Note that, not all the straps in the voltage area are extended out to core ring. The number of straps extended from each side of the voltage area is controlled by the **-num_extend_straps** option.

* **boundary**

Extends the power straps to the top-level cell boundary and creates pins.

By default, PNS extends the power and ground straps to the rings inside the

voltage area (**-extend_strap voltage_area_ring**). ring(s) inside.
This option belongs to the ring constraints group and must be specified with either the **-ring_nets** or **-skip_ring** option, if there are existing rings.

-num_extend_straps number_extended
Specifies the number of power straps extended out from each side of the voltage area to the core ring. The default is 4.
This option belongs to the ring constraints group and must be specified with either the **-ring_nets** or **-skip_ring** option, if there are existing rings.

-extend_strap_direction directions_to_extend
Specifies the directions in which to extend the straps from the voltage area to the core ring or boundary. You can specify one or more of the following keywords:
* **left**
* **right**
* **top**
* **bottom**
You can also use the keyword **all** to extend straps from all sides of the voltage area.
By default, PNS extends straps from all sides of the voltage area.
This option belongs to the ring constraints group and must be specified with either the **-ring_nets** or **-skip_ring** option, if there are existing rings.

-global
Specifies global constraints in the voltage area.
This option belongs to the global constraints group and is required when specifying global constraints.

-keep_floating_segments
Keeps dangling wires cut by hard macros or blockages in the voltage area.
By default, PNS removes dangling wires.
This option belongs to the global constraints group.

-no_stack_via
Disallows the use of stacked vias in the voltage area. Vias are dropped only on adjacent layers.
By default, PNS generates stacked via.
This option belongs to the global constraints group.

-no_same_width_sizing
Allows power and ground straps to have different widths in the voltage area.
By default, PNS creates straps with the same width for power and ground nets.
This option belongs to the global constraints group.

-optimize_tracks
Optimizes wire width in the voltage area to lower the routing usage by power and ground straps.
By default, wire width is not optimized.
This option belongs to the global constraints group.

-no_routing_over_hard_macros
Disables routing of power and ground straps across hard macros.
By default, power and ground straps can be routed across hard macros.
This option belongs to the global constraints group.

```

-no_routing_over_plan_groups
    Disables routing of power and ground straps across plan groups.
    By default, power and ground straps can be routed across plan groups.
    This option belongs to the global constraints group.

-no_routing_over_soft_macros
    Disables routing of power and ground straps across soft macros.
    By default, power and ground straps can be routed across soft macros.
    This option belongs to the global constraints group.

-ignore_blockages
    Generates power and ground straps despite the presence of blockages.
    By default, blockages are not ignored.
    This option belongs to the global constraints group.

-allow_routing_over_voltage_area
    Allows routing of power and ground straps of the voltage area to cross other
    voltage areas. This option is needed when synthesizing inner nested voltage
    areas.
    By default, routing of power and ground straps cannot cross other voltage
    areas.
    This option belongs to the global constraints group.

```

DESCRIPTION

This command defines power network synthesis (PNS) constraints for the specified voltage area. It is used for multivoltage power network synthesis and addresses four types of constraints: synthesis, layer, ring, and global.

You can specify only one group of constraints in each command. The options specifying the constraints for each group follow the required options. For synthesis constraints, you must specify the **-nets** option, unless you are applying synthesis constraints to the primary power and ground nets defined in the UPF. For layer constraints, you must specify the **-layer** option. For ring constraints, you must specify the **-ring_nets** option, unless you are defining ring constraints for the nets associated with the synthesis constraints, or you are defining constraints for the existing rings, in which case you must specify the **-skip_ring** option. For more information, see the descriptions for the ring group options. For global constraints, you must specify the **-global** option.

You can apply constraints to only one voltage area at a time.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to specify power network synthesis constraints to the MULTIPLIER, INST, and DEFAULT_VA voltage areas. The MULTIPLIER voltage area uses the VDD1 power supply at 1.1V. The INST voltage area is a power-down voltage area that uses the VDD2 power supply at 0.9V. It uses the permanent VDD2 power net and

the virtual VDD2_Virtual power net. The DEFAULT_VA voltage area uses the VDD power supply at 1.5V. The voltage areas have a common ground net, VSS.

```
prompt> set_fp_rail_voltage_area_constraints \
-voltage_area MULTIPLIER -nets {VDD1 VSS} \
-voltage_supply 1.1 -power_budget 120 \
-target_voltage_drop 80

prompt> set_fp_rail_voltage_area_constraints \
-voltage_area INST -nets {VDD2+VDD2_Virtual VSS} \
-voltage_supply 0.9 -power_budget 60 \
-target_voltage_drop 90

prompt> set_fp_rail_voltage_area_constraints \
-voltage_area DEFAULT_VA -nets {VDD VSS} \
-voltage_supply 1.5 -power_budget 200 \
-target_voltage_drop 100
```

The following example shows the commands that apply the same voltage area constraints for a design in which the primary power and ground nets are defined in the UPF, so the **-nets** option is not required.

```
prompt> set_fp_rail_voltage_area_constraints \
-voltage_area MULTIPLIER \
-voltage_supply 1.1 -power_budget 120 \
-target_voltage_drop 80

prompt> set_fp_rail_voltage_area_constraints \
-voltage_area INST \
-voltage_supply 0.9 -power_budget 60 \
-target_voltage_drop 90

prompt> set_fp_rail_voltage_area_constraints \
-voltage_area DEFAULT_VA \
-voltage_supply 1.5 -power_budget 200 \
-target_voltage_drop 100
```

The following example shows how to specify layer constraints for the MULTIPLIER voltage area. Power and ground straps will be generated on the METAL5 METAL6 layers in the voltage area, with a maximum width of 2.5 microns and a minimum width of 1.0 microns.

```
prompt> set_fp_rail_voltage_area_constraints \
-voltage_area MULTIPLIER -layer {METAL5} \
-max_width 2.5 -min_width 1.0

prompt> set_fp_rail_voltage_area_constraints \
-voltage_area MULTIPLIER -layer {METAL6} \
-max_width 2.5 -min_width 1.0
```

The following example shows how to create a core ring and a voltage area ring for the VDD1 net and extend eight VDD1 straps from the left side of the MULTIPLIER voltage area to the core ring.

```
prompt> set_fp_rail_voltage_area_constraints \
```

```
-voltage_area DEFAULT_VA -ring_nets {VDD VDD1 VSS} \
-horizontal_ring_layer METAL7 \
-vertical_ring_layer METAL8

prompt> set_fp_rail_voltage_area_constraints \
-voltage_area MULTIPLIER -ring_nets {VDD1 VSS} \
-horizontal_ring_layer METAL5 \
-vertical_ring_layer METAL6 \
-extend_strap core_ring \
-num_extend_straps 8 \
-extend_strap_direction {left}
```

SEE ALSO

`report_fp_rail_voltage_area_constraints(2)`
`synthesize_fp_rail(2)`

set_fp_relative_location

Specifies a constraint to place a macro relative to an anchor object.

SYNTAX

```
status set_fp_relative_location
-name constraint_name
-target_cell cell_name
[-target_orientation N | S | E | W | FN | FS | FE | FW]
[-target_corner bl | br | tl | tr]
[-anchor_object object_name]
[-anchor_corner bl | br | tl | tr]
[-x_offset distance]
[-y_offset distance]
```

Data Types

<i>constraint_name</i>	string
<i>cell_name</i>	string
<i>object_name</i>	string
<i>distance</i>	float

ARGUMENTS

```
-name constraint_name
      Specifies name of the constraint.

-target_cell cell_name
      This option specifies the name of the macro cell which the constraint will
      be applied.

-target_orientation N | S | E | W | FN | FS | FE | FW
      Specifies the orientation to place the target cell. The value can be one of
      the 8 possible choices represented by the following strings.
      N, S, E, W, FN, FS, FE, FW.

      The default is N.

-target_corner bl | br | tl | tr
      Specifies which corner of the target cell to apply the constraint on. The
      value can be one of the 4 possible choices represented by the following st
      rings:
      bl, br, tl, tr.

      These 4 strings represent bottom-left, bottom-right, top-left, and top-
      right,
      respectively. The default is bl.
```

```

-anchor_object object_name
    Specifies the name of the anchor object. An anchor object can be a plan group,
    a fixed macro cells, a macro cell that has its own relative location constraint,
    or core area. This option is optional. Default is core area.

-anchor_corner bl | br | tl | tr
    Specifies the corner of the anchor object's bounding box that this constraint
    uses. The value can be one of the 4 possible choices represented by the
    following strings:
    bl, br, tl, tr.

    These 4 strings represent bottom-left, bottom-right, top-left, and top-right,
    respectively. The default is bl.

-x_offset distance
    Specifies the distance from the target corner to the anchor corner in X dimension.
    The value can be positive, negative or zero. A positive value would indicate the target corner being on the right side of the the anchor corner, and a negative value would result in the target corner being on the left side of the anchor corner, while a value of zero would mean the target corner has the same X coordinate as the anchor corner. The default is zero.

-y_offset distance
    Specifies the distance from the target corner to the anchor corner in Y dimension.
    The value can be positive, negative or zero. A positive value would indicate the target corner being higher than the the anchor corner, and a negative value would result in the target corner being lower than the anchor corner, while a value of zero would mean the target corner has the same Y coordinate as the anchor corner. The default is zero.

```

DESCRIPTION

The **set_fp_relative_location** command specified a location constraint of a macro cell relative to an anchor object. The macro cell's location will be determined by the parameters given. These location constraints will be respected by create_fp_placement command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to specify a relative location constraint on cell

"A1"'s top-right corner with respect to the top-left corner of plan group "G1".

```
prompt>set_fp_relative_location \
      -name rp1 \
      -target_cell "A1" \
-target_orientation "S" \
-target_corner "tr" \
-anchor_object "G1" \
-anchor_corner "tl" \
      -x_offset 150 \
      -y_offset 10
```

SEE ALSO

`create_fp_placement(2)`
`remove_fp_relative_location(2)`
`extract_fp_relative_location(2)`

set_fp_trace_mode

Marks a design and then loads the design in trace mode.

SYNTAX

```
status set_fp_trace_mode
[-verbose]
[-verbose]
```

ARGUMENTS

-verbose
Turns on verbose mode for trace mode marking and loading.

EXAMPLE

The following example shows a basic output of the set_fp_trace_mode command.

```
prompt> get_fp_trace_mode

Design is not in trace mode
0

prompt> set_fp_trace_mode

set_fp_voltage_area_constraints

Sets voltage area feedthrough constraints that are used by the global routing and the **analyze_fp_routing** command to create logical pins on voltage areas.

SYNTAX

```
status set_fp_voltage_area_constraints
[-allow_feedthroughs true | false]
[-create_feedthrough_module true | false]
[-exclude_feedthroughs nets]
[voltage_areas]
```

Data Types

<i>nets</i>	collection
<i>voltage_areas</i>	collection

ARGUMENTS

-allow_feedthroughs true | false

Specifies whether feedthrough ports can be created on the specified voltage areas.

By default, this option is **false** (no feedthrough ports are created).

If set to **true**, global routing and **analyze_fp_routing** can create feedthrough ports in the logical child cell. Each top-level net for which a feedthrough port is created is split into a set of new top-level nets and child-level nets (if feedthrough nets were created for the child net). Directions are assigned for the newly created feedthrough ports.

-create_feedthrough_module true | false

Specifies whether a new logical module should be created to hold the feedthroughs for a voltage area

By default, this option is **false** (no new feedthrough module is created).

If this option is set to **true**, the global router creates only feedthroughs that have no connection inside the voltage area. These internally unconnected feedthroughs, which are sometimes called "pure" feedthroughs, can be assigned ports on a new "feedthrough only module" without affecting the interface ports on the original voltage area modules. The **analyze_fp_routing** command creates a new hierarchy module and assigns the feedthrough ports to this new module, rather than to some existing logical module. The new hierarchy module is a child of the first common ancestor of all the logical modules in the voltage area, and it also is a member of the voltage area. The new hierarchy module becomes part of the logical netlist. It is initially empty, but buffers could be added later for the feedthroughs. The name of those new modules will be "VoltageAreaName_ft_module", where "VoltageAreaName" is the name of voltage area to which the new module belongs. When this option is selected, router will route nets such that only pure feedthrough can be created and analyze_fp_routing will create those new modules and put those pure feedthroughs on those modules. In the case where more than two voltage areas are fully abutted and the net has connections to all those abutted voltage areas, router can not route net without creating regular feedthrough. In suchy case, analyze_fp_routing will skip such net and no feedthrough would

be created.

This option is ignored unless it is used together with the **--allow_feedthroughs true** option.

-exclude_feedthroughs nets
 Excludes feedthrough port creation on the specified nets.
 The effect of this option is not cumulative. A subsequent call to **set_fp_voltage_area_constraints** that uses this option overrides the previous setting. For example, after the following successive calls to **set_fp_voltage_area_constraints**, feedthrough exclusion applies only to net B:
`set_fp_voltage_area_constraints -allow_feedthroughs true \
-exclude_feedthroughs [get_nets A]
set_fp_voltage_area_constraints -allow_feedthroughs true \
-exclude_feedthroughs [get_nets B]`
 To remove all nets previously specified with this option from feedthrough exclusion, use this option with an empty collection as argument, **-exclude_feedthroughs {}**.
 This option is ignored unless it is used together with the **--allow_feedthroughs true** option.

voltage_areas
 Specifies a collection of voltage areas to which the specified constraints apply.
 By default, the specified constraints apply to all voltage areas.

DESCRIPTION

This command allows you to set voltage area feedthrough constraints to be honored during global routing and **analyze_fp_routing**. The voltage area constraints are saved in the Milkyway database.

Use **set_fp_voltage_area_constraints -allow_feedthroughs false** to reset all constraint values to their defaults.

Multicorner Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following command allows feedthrough nets to be created on voltage areas A, B, and C.

```
prompt> set_fp_voltage_area_constraints -allow_feedthroughs true \
[get_voltage_areas A B C]
```

SEE ALSO

set_groute_options

Sets global router cell-persistent options.

SYNTAX

```
status set_groute_options
[-name ]
[-value ]
[-default]
```

ARGUMENTS

-name *name*
Specifies the name of the option to be set. Use command **report_groute_options** to check for valid names.

-value *value*
Specifies the value of the option to be set. Use command **report_groute_options -name** to check for valid range, type, default value, current value and a brief description of a named option.

-default
Set all groute options to their default values. To set a specific groute option to its default value, use "-name" and "-value" arguments. Use command **report_groute_options** to check for default value.

DESCRIPTION

The **set_groute_options** command sets options to tune global router operation. These settings are persistent in the Milkyway design. This command saves cell-persistent options in cell data base, and marks cell as being modified. To permanently save these options, you have to save cell upon exit. This command is optional, if you want defaults to apply. All options are optional too. However, if you want to set a specific option value, "-name" and "-value" have to be specified. To reset all options to their default values, use "-default" argument. To print all available global router options, their current value, default value, range, type and a brief description, use command **report_groute_options**

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> set_groute_options -name accessPolyPin -value 0
prompt> set_groute_options -default
```

SEE ALSO

`report_groute_options(2)`

set_hierarchy_color

Sets colors on all leaf cells descended from top hierarchical cells in the current design or hierarchical cells in the specified collection.

SYNTAX

```
int set_hierarchy_color
-color color_Id | -cycle_color
[collection]
```

Data Types

<i>color_Id</i>	integer
<i>collection</i>	collection

ARGUMENTS

-color *color_Id*

Specifies a Milkyway color Id, which is used to set color on all leaf cells descended from hierarchical cells.

The **-color** option is mutually exclusive with the **-cycle_color** option; use one of the options, but not both.

-cycle_color

Specifies to automatically generate different colors for each hierarchical cell and sets the color on all leaf cells descended from the hierarchical cell.

The **-cycle_color** option is mutually exclusive with the **-color** option; use one of the options, but not both.

collection

Specifies a collection of objects on which to set the colors. Sets the colors on all leaf cells descended from hierarchical cells in the specified collection.

This argument can be used with **-color** or **-cycle_color**.

DESCRIPTION

The **set_hierarchy_color** command sets the colors on leaf cells descended from top hierarchical cells in the current design, or hierarchical cells in the specified collection. The colors set on cells are used to paint the cells on some graphic windows, such as Layout View.

When **-color** and *collection* are specified, the command sets the color on all leaf cells descended from hierarchical cells in the collection. When **-color** is specified without *collection*, the command sets the color on all leaf cells in the current design.

When **-cycle_color** and *collection* are specified, the command generates a different color for each hierarchical cell in the collection, and sets the color on all leaf cells descended from that hierarchical cell.

When **-cycle_color** is specified without *collection*, the command generates a different color for each top-level hierarchical cell in the current design, and sets the color on all leaf cells descended from that hierarchical cell.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example generates different colors for each top hierarchical cell in the current design, and sets the color on all leaf cells in the hierarchical cell:

```
prompt> set_hierarchy_color -cycle_color
```

The following example sets the color with Milkyway color Id 8 on all leaf cells inside the RES_1113 hierarchical cell:

```
prompt> set_hierarchy_color -color 8 [get_cell RES_1113]
```

SEE ALSO

`unset_hierarchy_color(2)`

set_host_options

Controls the number of threads used by commands in the parent (master) process. Also controls the options used by commands that can run distributed jobs.

SYNTAX for the Parent (Master) Process

```
status set_host_options  
[-max_cores number_of_threads]
```

Data Types for the Parent (Master) Process

<i>number_of_threads</i>	int
--------------------------	-----

SYNTAX for the Child (Slave) Processes

```
status set_host_options  
[-name options_name]  
[-num_processes number_of_jobs_or_partitions]  
[-max_cores number_of_threads]  
[-timeout timeout]  
[-submit_command batch_submission_command_path]  
[-submit_options batch_submission_command_options]  
[-32bit]  
[-pool lsf | grd]  
[list_of_hosts]
```

Data Types for the Child (Slave) Processes

<i>options_name</i>	string
<i>number_of_jobs_or_partitions</i>	int
<i>timeout</i>	int
<i>batch_submission_command_path</i>	string
<i>batch_submission_command_options</i>	string
<i>list_of_hosts</i>	list

ARGUMENTS

-max_cores number_of_threads

If this option is specified by itself, it controls the maximum number of threads that can be used by thread-based commands in the current (main) job. If it is specified as part of a host or pool specification, it controls the number of threads each distributed slave job on the specified hosts or pool are allowed to use. In both cases, the value is a maximum, so some commands might use fewer threads than the specified value, but in no case would they use more.

-name options_name

Specifies a name for this collection of options. The name can later be

specified in the `remove_host_options` command to remove only these particular options. If you do not specify this option, the tool generates a name. If a set of options with the specified name already exists, the specified options replace the existing options.

-num_processes number_of_jobs_or_partitions

Controls the level of parallelism used for job submission. If you are defining an LSF, GRD, or custom pool, this is the maximum total number of jobs that can be submitted to it. If you are defining a collection of named hosts, this is the maximum number of jobs per host that can be started on those hosts. You can restrict the number of active jobs to a specified number based on hardware or license resource restrictions.

The default is no limit.

-timeout timeout

Specifies the job submission timeout value in seconds.

If the submitted jobs do not become running jobs within the specified timeout, they are killed. This is to prevent hanging jobs in the queuing system.

If you do not specify this option, the system waits as long as needed for jobs to start.

-submit_command batch_submission_command_path

Specifies the full path name of the LSF, GRD, or custom job submission program.

If you do are defining a simple pool of machines and do not specify this option, **rsh** is used as the submission program.

If you specify the **-pool** option and do not specify this option, the system might be able to locate and use the standard LSF or GRD job submission programs.

-submit_options batch_submission_command_options

Specifies any options to be passed to the LSF, GRD, rsh, or custom job submission program.

-32bit

Indicates that the program used by the distributed commands for executing their slave jobs is run in 32-bit mode.

If you do not specify this option, 64-bit mode is used if possible; otherwise, 32-bit mode is used.

-pool lsf | grd

Used by some commands to optimize their behavior for the specified type of queuing system.

If you are defining a queuing system, you must specify either this option or the **-submit_command** option.

If you are defining a simple pool of machines, this option is meaningless and is not allowed.

list_of_hosts

Specifies a list of hosts that are used to run distributed jobs.

If you specify this argument, the **-pool** and **-timeout** options are meaningless and are not allowed.

DESCRIPTION

IC Compiler supports several commands that can be run in distributed mode, in which a task is broken up into many pieces and each subproblem is run independently. The **set_host_options** command defines the parameters for running a command in distributed mode.

It allows for simple setup for the new user and also for arbitrarily complex setup for the user with more sophisticated needs.

In its simplest form, the command is used to control the number of threads used by multicore commands. A multicore command can use fewer threads than this maximum, but the command can never exceed the stated maximum.

The command is versatile enough to interface to LSF, GRD, or a custom job-submission system, and has a mode in which a listed set of machines are used with the rsh command to execute remote jobs without having a queuing system at all.

If you are using a queuing system such as LSF, GRD, or a custom queuing system, you use the **set_host_options** command to specify a path to the batch submission system and a queuing-system-specific set of command-line options that are passed along to the queuing system. These are typically used to ask for specific resources or otherwise control the queuing system. You can also control the submit timeout to make sure that jobs don't get stuck forever in a queuing system.

If you are not using a queuing system, you can still use distributed processing by providing a list of host machines, which the tool then uses to launch remote jobs with the rsh command.

If you run the **set_host_options** command multiple times, the settings are additive. This allows you to define different numbers of jobs to different machines. Because you can specify more than one host, all hosts with the same settings can be configured with a single call, minimizing the number of calls that must be made to build up the host options set.

You can name the collection of options that the **set_host_options** command creates by using the **-name** option. If you do not specify a name, IC Compiler automatically generates a name. You can use the name with the **remove_host_options** command to remove only the options of that name.

You can use the **report_host_options** command to report information about the defined host option sets.

There is a great deal of power and flexibility in the **set_host_options** command. You should start by using a single set of options until you fully understand how host option sets are made and how they are used by distributed commands. The EXAMPLES section below provides examples growing in complexity from basic to complex.

EXAMPLES

The following example sets up multicore operation within the parent process.

```
prompt> set_host_options -max_cores 4  
...
```

```
## The following command uses max 4 threads.  
prompt> some_threaded_command ...
```

The following distributed job example shows the use of host mode. It sets the timeout as well, so that if a submitted job doesn't start within 1200 seconds, the job will be killed.

```
prompt> set_host_options -timeout 1200 -num_processes 2 sleepy doc  
prompt> set_host_options -timeout 1200 -num_processes 4 grumpy  
...  
## This runs 8 jobs at once.  
prompt> some_distributed_command ...
```

Note that in the previous example there are a total of 8 job slots available (2 each from sleepy and doc, and 4 from grumpy).

The following example shows the use of LSF mode. It sets the maximum number of jobs that can submitted to 12, chooses the amd64 queue, and names this set of options lsfOptions. This name can be used later to identify or delete this set of options.

```
prompt> set_host_options -pool lsf -num_processes 12 \  
-name "lsfOptions" \  
-submit_command /lsf/bin/bsub -submit_options "-q amd64"  
...
```

The following example shows the use of a non-standard pool. It sets the maximum number of jobs that can submitted to 8, defines the custom script for job submission, and names this set of options customOptions. This name can be used later to identify or delete this set of options.

```
prompt> set_host_options -num_processes 8 -name "customOptions" \  
-submit_command /usr/local/bin/my_submit_command  
...
```

SEE ALSO

set_ideal_latency

Specifies ideal network latency.

SYNTAX

```
string set_ideal_latency
[-rise | -fall]
[-min | -max]
delay
object_list
```

Data Types

<i>delay</i>	float
<i>object_list</i>	list

ARGUMENTS

-rise | -fall

Specifies whether the latency is for data rise or data fall transition. If you do not specify **-rise** or **-fall**, both values are set. The **-rise** and **-fall** options are mutually exclusive.

-min | -max

Specifies whether the latency is to be used for minimum delay analysis or maximum delay analysis. By default, the delay is used for both maximum and minimum delay analysis. The **-min** and **-max** options are mutually exclusive.

delay

Specifies the ideal latency value on pins in the ideal network. The delay must be expressed in units consistent with the technology library used during optimization. For example, if the technology library specifies delay values in nanoseconds, *delay* must be expressed in nanoseconds.

object_list

Specifies a list of leaf cell pins or top-level ports that are the startpoints of the timing arcs for which ideal latency is to be set.

DESCRIPTION

Sets the ideal latency on top-level ports and leaf cell pins of the ideal network.

Design Compiler assumes ideal timing for ideal networks and ideal nets, which means pins have a specified ideal latency (from the **set_ideal_latency** command) or zero ideal latency by default. The ideal network is normally used for pre-layout to reduce runtime by avoiding unnecessary DRC optimization and retiming. Ideal latency provides an estimate of the ideal network or ideal nets for pre-layout.

The specified latency value overrides the internally-estimated cell delay value and net delay value. If the specified pins do not belong to the ideal network, ideal nets, or auto disable drc nets, the **report_ideal_network** command generates an error

message and the *delay* value is not used for those pins.

The **set_ideal_latency** command affects all pins in the transitive fanout of the pins or ports. The total ideal latency at an ideal boundary pin is the sum of latency on the ideal network source and all ideal latencies on the path.

You can use **set_ideal_latency** for pins at lower levels of the design hierarchy. Pins are specified in the form of "INSTANCE1/INSTANCE2/PIN_NAME."

To list ideal latency values, use the **report_ideal_network** command.

To remove ideal latency values from a design, use the **remove_ideal_latency** or **reset_design** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example specifies a rise latency of 1.2 and a fall latency of 0.9 for ports named *A*, *B*, and *C*.

```
prompt> set_ideal_latency 1.2 -rise {A B C}
prompt> set_ideal_latency 0.9 -fall {A B C}
```

SEE ALSO

```
current_design(2)
remove_ideal_latency(2)
remove_ideal_network(2)
remove_ideal_transition(2)
report_ideal_network(2)
report_timing(2)
set_ideal_net(2)
set_ideal_network(2)
set_ideal_transition(2)
```

set_ideal_net

This command is replaced by `set_ideal_network -no_propagate` under the hood. It is recommended to use `set_ideal_network` instead of `set_ideal_net`.

SYNTAX

```
status set_ideal_net
net_list
```

Data Types

`net_list` list

ARGUMENTS

`net_list`

Specifies a list of names of nets on which the **ideal_net** attribute is to be set. These nets must be visible from the current design.

DESCRIPTION

Starting from the 2004.12 release, the `set_ideal_net` and `set_ideal_network` commands are combined. The `set_ideal_net` command is replaced by `set_ideal_network -no_propagate` command under the hood.

Global driver pins of the specified nets are marked as sources of ideal network. These nets must be visible in the current design. Design Compiler treats a net as an ideal net if all global driver pins of the net are ideal. By default, Design Compiler treats all clock nets as ideal nets. However, this does not include the logic gates in the networks, and the nets driven by those logic gates. The ideal properties of the net's global driver pins do not propagate through logic gates. However, they propagate through hierarchies. Once set on the net's global driver pins, the ideal properties are enabled on all the nets that are electrically connected to those pins.

To prevent clock nets from being treated as ideal nets, use `set_auto_disable_drc_nets -clock false` or `set_propagated_clock -all_clocks()`.

After `set_propagated_clock -all_clocks()` has executed, the **ideal_net** attribute is not reported by `report_net`.

Ideal nets are networks of nets that are free from `max_capacitance`, `max_fanout`, and `max_transition` design rule constraints. Ideal nets are useful for reducing DRC violations caused by clock trees, because these networks usually have high `max_capacitance` and `max_fanout` violations. Ideal nets use ideal latency specified by the `set_ideal_latency` command and ideal timing specified by the `set_ideal_transition` for timing calculation. By default, zero ideal latency and zero transition are used. To automatically spread ideal attributes through a network, use the `set_ideal_network` command without the `-no_propagate` option.

Design Compiler automatically sets `size_only` on the cells of the ideal network

sources. And ideal net implies that this net is dont_touch. Note that Design Compiler may still optimize away combinational cells in the fanout of the ideal net. However, Design Compiler guarantees that the ideal network sources are never lost. To automatically set clock, constant or scan nets in the design as ideal, use the **set_auto_disable_drc_nets** command.

Use **remove_ideal_net** command to revert the result from **set_ideal_net** command in the current design. **set_auto_disable_drc_nets -none** removes the **auto_disable_drc_net** attribute. **reset_design** removes all attributes from the design, including both the ideal attributes and **auto_disable_drc_net** attributes; however, by default Design Compiler still treats clock networks as ideal nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the **ideal_net** attribute on nets in design CLOCK_GEN:

```
prompt> current_design CLOCK_GEN
prompt> set_ideal_net [get_nets]
```

SEE ALSO

```
remove_ideal_net(2)
reset_design(2)

set_ideal_latency(2)
set_ideal_network(2)
set_ideal_transition(2)
set_dont_touch(2)
set_dont_touch_network(2)
```

set_ideal_network

Marks a set of ports or pins in the current design as sources of an ideal network. This disables timing update and optimization of cells and nets in the transitive fanout of the specified objects.

SYNTAX

```
integer set_ideal_network
object_list
[-dont_care_placement]
[-no_propagate]
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of objects (ports, pins, or nets) to mark as the sources of an ideal network. If more than one object name is specified, each must be enclosed in quotation marks or braces {}. The source objects are input ports on the design or any internal pin, except for pins at hierarchical boundaries. If nets are provided, all of the nets' global driver pins are marked as ideal network sources, and the corresponding ideal network attributes are actually set on all of the global driver pins of the specified nets. These objects must be visible from the current design.

The **set_ideal_network** command accepts nets only when you specify the **-no_propagate** option.

-dont_care_placement

Indicates that the ideal network is not considered in placement. The nets in the ideal network are treated as disconnected. Random locations are assigned to ideal network cells. By default, the ideal network is placed at the lowest priority.

-no_propagate

Indicates that the ideal network is not propagated through logic gates, but it still propagates through hierarchies. Ideal properties are enabled on all nets that are electrically connected to ideal network sources. By default, this option is off.

DESCRIPTION

This command marks a set of ports or pins in the current design as sources of an ideal network. Ideal networks are an extension of ideal nets that incorporate automatic propagation of the **ideal** attribute. You specify only the source of the network; the **compile** command treats all nets, cells, and pins on the transitive fanout of these objects as ideal. The ideal property is automatically spread by the tool and respread as necessary during **compile** optimizations. The criteria for propagating the ideal property, starting at the source pins and ports, are as

follows:

- A pin is marked as ideal if you specify it by using the **set_ideal_network** command if it is either a driver pin and its cell is ideal or it is a load pin attached to a net that is ideal.
- A net is marked as ideal if all of its driving pins are ideal.
- A combinational cell is marked as ideal if all of its input pins are either ideal or attached to a constant net (and other input pins are ideal). Objects with the **case analysis** attribute set are not treated as constant.

Propagation traverses through combinational cells but stops at sequential cells. If an ideal network overlaps a clock network, the clock timing overrides the ideal timing for the clock part of the network.

In addition to disabling timing updates and timing optimizations, all cells and nets in the ideal network have the **dont_touch** attribute set.

The **size_only** attribute is set on all cells of ideal network sources. If nets are specified, **size_only** is set on all cells that are cells of the specified nets' global driver pins. This guarantees that ideal network sources are not optimized away by compile.

NOTE: The implied **size_only** attribute set by this command overrides the four **FALSE** attribute values set by the **set_size_only** command. Use the **report_cell** command to determine if a cell is size_only or not.

DRC checking is turned off so the nets in an ideal network are free of **max_capacitance**, **max_fanout**, and **max_transition** design rule constraints. Disabling all of these features improves runtime and timing optimization; for example, by not resetting and scanning networks that you might want synthesized separately when using the **compile** command.

The latency and transition times of an ideal network are 0 by default, but you can override them by using the **set_ideal_latency** and **set_ideal_transition** commands.

If the **ideal_network** attribute is set on floating objects in a design, these objects are still optimized away during compile.

To reverse the effect of the **set_ideal_network** command, use the **remove_ideal_network** command and specify the source pins or ports for the network. Timing, source pins, and boundary pins of an ideal network are displayed by using the **report_ideal_network** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates an ideal network on objects in a design named *CLOCK_GEN*.

set_ideal_network

2372

```
prompt> current_design CLOCK_GEN
prompt> set_ideal_network {port1 port2}
```

`set_ideal_transition(2)`
`set_size_only(2)`

set_ideal_transition

Specifies ideal transition for the ideal network & ideal nets.

SYNTAX

```
string set_ideal_transition
[-rise | -fall]
[-min | -max]
transition_time
object_list
```

Data Types

<i>transition_time</i>	float
<i>object_list</i>	list

ARGUMENTS

-rise | -fall

Indicates whether the specified transition time is applicable for rising or falling transition. If you do not specify **-rise** or **-fall**, both values are set. The **-rise** and **-fall** options are mutually exclusive.

-min | -max

Specifies whether the transition is to be used for minimum delay analysis or maximum delay analysis. By default, the delay is used for minimum and maximum delay analysis. The **-min** and **-max** options are mutually exclusive.

transition_time

Specifies the ideal transition value on the pins in an ideal network. The transition time must be expressed in units consistent with the technology library used during optimization. For example, if the technology library specifies transition values in nanoseconds, *transition_time* must be expressed in nanoseconds.

object_list

Specifies a list of leaf cell pins or top-level ports that are the startpoints of the timing arcs for which ideal transition is set.

DESCRIPTION

Sets the ideal transition on top-level ports and leaf cell pins of an ideal network.

Design Compiler assumes ideal timing for the ideal network, which means pins have a specified ideal transition (from the **set_ideal_transition** command) or zero ideal transition by default. The ideal network is normally used for pre-layout to reduce runtime by avoiding unnecessary DRC optimization and retiming. Ideal transition provides an estimate of the ideal network for pre-layout.

The specified transition value overrides the internally-estimated cell and net transition value. If the specified pins do not belong to the ideal network, an error

message is generated by the **report_ideal_network** command and *transition_time* is not used for those pins.

The ideal transition at an ideal boundary pin is the ideal transition of the closest pin with specified ideal transition.

You can use **set_ideal_transition** for pins at lower levels of the design hierarchy. Pins are specified in the form of "INSTANCE1/INSTANCE2/PIN_NAME."

To list ideal transition values, use the **report_ideal_network** command.

To remove the ideal transition values from a design, use the **remove_ideal_transition** or **reset_design** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example specifies a rise transition of 1.2 and a fall transition of 0.9 for ports named A, B, and C.

```
prompt> set_ideal_transition 1.2 -rise {A B C}
prompt> set_ideal_transition 0.9 -fall {A B C}
```

SEE ALSO

```

remove_ideal_transition(2)
report_ideal_network(2)
report_timing(2)
set_ideal_latency(2)
set_ideal_network(2)
```

set_ignore_cell_timing

Skips the analysis of part of the design.

SYNTAX

```
int set_ignore_cell_timing  
cell_list
```

Data Types

cell_list list

ARGUMENTS

cell_list
Specifies a collection of cells on which the **ignore_cell_timing** attribute is to be set. These cells must be visible from the current design.

DESCRIPTION

The `set_ignore_cell_timing` command is used in the exploration phase of the design process to skip the analysis of part of the design. If there is one or more hierarchichal blocks that are either incomplete, or require large runtimes they can be set as ignored so that optimization and analysis can concentrate on other parts of the design. Leaf cells may also be set as ignored.

The effect of `set_ignore_cell_timing` is to suppress all timing paths that are within, through, into, or out of that cell. It also suppresses any changes to the netlist due to timing or DRC reasons.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following example sets the **ignore_cell_timing** attribute on cells in design CLOCK_GEN.

```
prompt> current_design CLOCK_GEN  
prompt> set_ignore_cell_timing get_cells(cell)
```

SEE ALSO

```
remove_ignore_cell_timing(2)  
set_ideal_network(2)
```

set_ignored_layers

Sets ignored routing layers for congestion analysis and RC estimation. This command can also set design minimum and maximum layers.

SYNTAX

```
int set_ignored_layers
[-rc_congestion_ignored_layers names]
[-min_routing_layer name]
[-max_routing_layer name]
```

ARGUMENTS

-rc_congestion_ignored_layers *names*

Lists the routing layer names to be ignored in congestion analysis and RC estimation. This option will remove the layers from both RC and congestion estimation, but will not affect the behavior of the router.

-min_routing_layer *name*

Specify the design min_routing_layer. The following routing will respect this setting. In order to ensure that the RC and congestion estimation stay in-sync with the router controls, when the design min routing layer is set, DC-Topography will always mark all the routing layers below this layer as "ignored layers" for RC and congestion estimation.

-max_routing_layer *name*

Specify the design max_routing_layer. The following routing will respect this setting. In order to ensure that the RC and congestion estimation stay in-sync with the router controls, when the design max routing layer is set, DC-Topography will always mark all the routinger layers above this layer as "ignored layers" for RC and congestion estimation.

DESCRIPTION

You can use this command to set routing layers that can be ignored during congestion analysis and RC estimation. If a routing layer is ignored, congestion analysis and interconnect RC estimation do not use this layer. This command can be used when you don't want to route nets on certain routing layers. If you set the design minimum and maximum routing layers using this command, routing respects these settings. If you set the design minimum routing layer to a certain layer, this command automatically sets all the routing layers below this layer as "ignored" layers. The same behavior also applies to the design maximum routing layer setting.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example assigns the m5 and m6 layers to be ignored during congestion

analysis and RC estimation.

```
prompt> set_ignored_layers -rc_congestion_ignored_layers {m5 m6}
prompt> set_ignored_layers -min_routing_layer m2 -max_routing_layer m5
```

SEE ALSO

```
report_ignored_layers(2)
remove_ignored_layers(2)

```

set_input_delay

Sets input delay on pins or input ports relative to a clock signal.

SYNTAX

```
status set_input_delay
delay_value
[-clock clock_name]
[-clock_fall]
[-level_sensitive]
[-network_latency_included]
[-source_latency_included]
[-rise]
[-fall]
[-max]
[-min]
[-add_delay]
port_pin_list
```

Data Types

<i>delay_value</i>	float
<i>clock_name</i>	string
<i>port_pin_list</i>	list

ARGUMENTS

delay_value

Specifies the path delay. The *delay_value* must be in units consistent with the technology library used during optimization. The *delay_value* represents the amount of time the signal is available after a clock edge. This represents a combinational path delay from the clock pin of a register.

-clock *clock_name*

Specifies the clock to which the specified delay is related. If **-clock_fall** is used, **-clock *clock_name*** must be specified. If **-clock** is not specified, the delay is relative to time zero for combinational designs. For sequential designs, the delay is considered relative to a new clock with the period determined by considering the sequential cells in the transitive fanout of each port.

The *clock_name* can be either a string or collection of one object.

-clock_fall

Specifies that the delay is relative to the falling edge of the clock. The default is the rising edge.

-level_sensitive

Specifies that the source of the delay is a level-sensitive latch. This allows the tool to derive the setup and hold relationship for paths from this port as if the port is a level-sensitive latch. If **-level_sensitive** is not used, the input delay is treated as if it is a path from a flip-flop.

-network_latency_included
 Specifies that the clock network latency is not added to the input delay value. If this option is not specified, the clock network latency of the related clock is added to the input delay value. It has no effect if the clock is propagated or the input delay is not specified with respect to any clock.

-source_latency_included
 Specifies that the clock source latency is not added to the input delay value. If this option is not specified, the clock source latency of the related clock will be added to the input delay value. It has no effect if the input delay is not specified with respect to any clock.

-rise
 Specifies that *delay_value* refers to a rising transition on specified ports of the current design. If neither **-rise** nor **-fall** is specified, rising and falling delays are assumed to be equal.

-fall
 Specifies that *delay_value* refers to a falling transition on specified ports of the current design. If neither **-rise** nor **-fall** is specified, rising and falling delays are assumed equal.

-max
 Specifies that *delay_value* refers to the longest path. If neither **-max** nor **-min** is specified, maximum and minimum input delays are assumed equal.

-min
 Specifies that *delay_value* refers to the shortest path. If neither **-max** nor **-min** is specified, maximum and minimum input delays are assumed equal.

-add_delay
 Specifies whether to add delay information to the existing input delay or to overwrite. The **-add_delay** option enables you to capture information about multiple paths leading to an input port that are relative to different clocks or clock edges.
 For example, the following command removes all other maximum rise input delay from A, since **-add_delay** is not specified. Other input delay with a different clock or with **-clock_fall** is removed.
set_input_delay 5.0 -max -rise -clock phi1 {A}
 In the following example, **-add_delay** is specified. If there is an input maximum rise delay for A relative to clock *phi1* rising edge, the larger value is used. The smaller value will not result in critical timing for maximum delay. For minimum delay, the smaller value is used. If there is maximum rise input delay relative to a different clock or different edge of the same clock, it remains with the new delay.
prompt> set_input_delay 5.0 -max -rise -clock phi1 -add_delay {A}

port_pin_list
 Specifies a list of input port or internal pin names in the current design to which *delay_value* is assigned. If more than one object is specified, the objects are enclosed in quotes ("") or in braces ({}). If input delay is specified on a pin, the cell of the pin is set to size only to leave room for compile applying sizing on it.

DESCRIPTION

The **set_input_delay** command sets input path delay values for the current design. Used with **set_load** and **set_driving_cell**, the input and output delays characterize the operating environment of the current design.

A path starts from a primary input or clock of sequential element and ends at a sequential element or primary output. The **delay_value** to be specified is the delay between the startpoint and the object on which the **set_input_delay** is being set, relative to the clock edge.

The **set_input_delay** command sets input path delays on input ports relative to a clock edge. Input ports are assumed to have zero input delay, unless specified. For inout (bidirectional) ports, you can specify the path delays for both input and output modes.

To describe a path delay from a level-sensitive latch, use the **-level_sensitive** option. If the latch is positive-enabled, set the input delay relative to the rising clock edge; if it is negative-enabled, set the input delay relative to the falling clock edge. If time is being borrowed at that latch, add that time borrowed to the path delay from the latch when determining input delay.

The **characterize** command automatically sets input and output delay, drive, and load values based on the environment of a cell instance.

The timer adds input delay to path delay for paths starting at primary inputs and output delay for paths ending at primary outputs.

Use the **report_port** command to list input delays associated with ports.

To list input delays of internal pins, use **report_design**.

Use **remove_input_delay** or **reset_design** to remove input delay values.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets an input delay of 2.3 for ports IN1 and IN2 on a combinational design. Because the design is combinational, no clock is needed.

```
prompt> set_input_delay 2.3 {IN1 IN2}
```

The following example uses a clock collection and sets an input delay of 1.2 relative to the rising edge of CLK1 for all input ports in the design:

```
prompt> set_input_delay 1.2 -clock [get_clocks CLK1] [all_inputs]
```

The following example sets the input and output delays for the bidirectional port INOUT1. The input signal arrives at INOUT1 2.5 units after the falling edge of CLK1. The output signal is required at INOUT1 at 1.4 units before the rising edge of CLK2.

```
prompt> set_input_delay 2.5 -clock CLK1 -clock_fall {INOUT1}  
prompt> set_output_delay 1.4 -clock CLK2 {INOUT1}
```

The following example has three paths to the IN1 input port. One of the paths is relative to the rising edge of CLK1. Another path is relative to the falling edge of CLK1. The third path is relative to the falling edge of CLK2. The **-add_delay** option is used to indicate that new input delay information will not cause old information to be removed.

```
prompt> set_input_delay 2.2 -max -clock CLK1 -add_delay {IN1}  
prompt> set_input_delay 1.7 -max -clock CLK1 -clock_fall \  
      -add_delay {IN1}  
prompt> set_input_delay 4.3 -max -clock CLK2 -clock_fall \  
      -add_delay {IN1}
```

In this example, two different maximum delays and two minimum delays for port A are specified using **-add_delay**. Because the information is relative to the same clock and clock edge, only the largest of the maximum values and the smallest of the minimum values are maintained, in this 5.0 and 1.1. If **-add_delay** is not used, the new information overwrites the old information.

```
prompt> set_input_delay 3.4 -max -clock CLK1 -add_delay {A}  
prompt> set_input_delay 5.0 -max -clock CLK1 -add_delay {A}  
prompt> set_input_delay 1.1 -min -clock CLK1 -add_delay {A}  
prompt> set_input_delay 1.3 -min -clock CLK1 -add_delay {A}
```

set_input_transition

Sets the **max_transition_rise**, **max_transition_fall**, **min_transition_rise**, or **min_transition_fall** attributes to the specified transition values on the specified input and inout ports.

SYNTAX

```
int set_input_transition
    transition
    [-rise] [-fall] [-min] [-max]
    port_list
```

Data Types

<i>transition</i>	float
<i>port_list</i>	list

ARGUMENTS

transition

Specifies a nonnegative transition value to which the **max_transition_rise**, **max_transition_fall**, **min_transition_rise** or **min_transition_fall** attributes are to be set on the ports in *port_list*. The *transition* is the transition time of a slope that drives the port, such that a higher transition value means longer delays. Thus, a *transition* of 0 is infinite transition, or no delay between the ports and all that is connected to them. *transition* must be in units consistent with the technology library used during optimization.

-rise -fall

Indicates that the **rise** or **fall** attributes of *port_list* are to be set to *transition*. If neither is specified, both are set to *transition*.

-min -max

Indicates that the transition value is to be applied for minimum or maximum delay analysis. If no value is specified for minimum analysis, the maximum value is used.

port_list

Specifies a list of names of input or inout ports in the current design, on which the transition value is to be set. If you specify more than one port, you must enclose the ports in either quotes or braces ({}).

DESCRIPTION

Sets the **max_transition_rise**, **max_transition_fall**, **min_transition_rise** or **min_transition_fall** attributes to *transition* on specified input and inout ports in the current design.

Note: The **set_input_transition** command removes any corresponding rise or fall driving cell attributes and rise or fall drive attributes on the specified ports. If you want a fixed transition value, use **set_input_transition**, otherwise, use

set_driving_cell instead of **set_drive**, if possible.

To view transition information on ports, use **report_port -verbose**. To remove transition attributes from ports, use **remove_attribute**. The **reset_design** command removes all attributes from a design, including the transition attributes.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets the maximum rise and fall transition values of ports "A", "B", and "C" to 7.0.

```
prompt> set_input_transition 7.0 {A B C}
```

The following example sets the maximum rise and fall transition values of all input ports to 7 and sets the maximum rise transition value on port "B" to 11.

```
prompt> set_input_transition 7 [all_inputs]
prompt> set_input_transition -rise 11 B
```

The following example sets the minimum fall transition value 13 to port C

```
prompt> set_input_transition -fall -min 13.0 {C}
```

`set_driving_cell(2)`
`set_load(2)`

set_inter_clock_delay_options

Sets options for interclock delay balancing.

SYNTAX

```
status set_inter_clock_delay_options
[-balance_group source_objects]
[-balance_group_name string]
[-delay_offset float]
[-offset_to source_objects]
[-offset_from offset_from_obj]
[-offset_from_group string]
[-target_delay_clock target_clock_obj]
[-target_delay_value float]
[-honor_sdc true | false]
```

ARGUMENTS

-balance_group *source_objects*
Set a list of clocks as a group, inter clock delay balance will be performed among clocks in the group.

-balance_group_name *string*
Specifies a group name for the clocks defined under -balance_group. This option is optional.

-delay_offset *float*
Specifies delay offset value, positive value means clock under offset_to is lagging clock under offset_from, negative value means clock under offset_to is ahead clock under offset_from.

-offset_to *source_objects*
Specifies the clock(s) get set an offset from another clock under offset_from.

-offset_from *offset_from_obj*
Specifies the base clock for offset set to clock(s) under offset_to.

-offset_from_group *string*
Specifies a balance group for offset set to clock(s) under offset_to. The clock with the longest path delays in the balance group will be used as the offset from clock.

-target_delay_clock *target_clock_obj*
Specifies a clock of a target delay under -target_delay_value.

-target_delay_value *float*
Specifies target delay value of clock(s) under -target_delay_clock.

-honor_sdc true | false
Honors the latency defined in the Synopsys Design Constraints and performs interclock delay balance based on the command-line options, when this option

is set to **true**. When the option is either set to **false** (the default value) or not specified, the tool ignores the latency defined in the Synopsys Design Constraints, even if available.

DESCRIPTION

The **set_inter_clock_delay_options** command sets the options for inter clock delay balance. By using -delay_offset, -offset_to and -offset_from combined, the insertion delays under -offset_to are balanced to a clock under -offset_from with an offset value, a positive offset value means clocks under -offset_to are lagging and a negative value means -offset_to are ahead of the base clock under -offset_from or longest delay clock under balance group given through -offset_from_group. With -target_delay_clock and -target_delay_value, clocks under -target_delay_clock are balanced to the delay value specified by -target_delay_value. For different clocks with different target delay values, use separate set_inter_clock_delay_options command line. By using -balance_group and -balance_group_name, the inter clock balance will be performed among clocks in its own group.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command performs inter clock delay balance using set maximum target delay options:

```
prompt> balance_inter_clock_delay -max_target_delay 0.5
```

The following command performs inter clock delay balance for the *Clk1* clock tree to 0.5ns and /fIClk2 to 0.8ns, by using set_inter_clock_delay_options command and balance_inter_clock_delay command:

```
prompt> set_inter_clock_delay_options -target_delay_clock CLK1 -  
target_delay_value 0.5
```

```
prompt> set_inter_clock_delay_options -target_delay_clock CLK2 -  
target_delay_value 0.8
```

```
prompt> balance_inter_clock_delay
```

The following command performs inter clock delay balance for the *Clk1* clock tree lags *Clk2* by 0.5ns, by using set_inter_clock_delay_options command and balance_inter_clock_delay command:

```
prompt> set_inter_clock_delay_options -delay_offset 0.5 -offset_to Clk1 -  
offset_from Clk2
```

```
prompt> balance_inter_clock_delay
```

The following command performs inter clock delay balance by groups. Clk1 and Clk2 are in group1, while clk3, clk4 and clk5 are in group2 by using set_inter_clock_delay_options command and balance_inter_clock_delay command:

```
prompt> set_inter_clock_delay_options -balance_group "Clk1 Clk2" -
balance_group_name group1

prompt> set_inter_clock_delay_options -balance_group "Clk3 Clk4 Clk5" -
balance_group_name group2

prompt> balance_inter_clock_delay
```

SEE ALSO

[balance_inter_clock_delay\(2\)](#)

set_isolate_ports

Specifies the ports that are to be isolated from internal fanouts of their driver nets.

SYNTAX

```
int set_isolate_ports
[-type inverter | buffer]
[-driver cell_name]
[-force]
port_list
```

Data Types

<i>cell_name</i>	string
<i>port_list</i>	list

ARGUMENTS

-type inverter | buffer
Specifies that inverter pairs or buffers should be used to isolate the ports.

-driver *cell_name*
Indicates that the specified cell should be used to isolate the ports. The cell must be a buffer or an inverter in the target library. Note that Design Compiler may size the inserted cell, which could cause the actual driver cell to be different from the requested isolation cell. If this behavior is not desired, use the **-force** option in conjunction with the **-driver** option, to force the driver to be the requested isolation cell.

-force
Specifies that isolation must be performed on the ports, even if they do not need isolation because there are no internal loads on the nets driving the ports. Note: Isolation may not be performed if there is already a local buffer, inverter pair or cell corresponding to the specified isolation logic.

port_list
Specifies the ports in the current design that are to be isolated.

DESCRIPTION

The **set_isolate_ports** command specifies the input or output ports in the current design that are to be isolated. For an output port the **compile** command attempts to ensure that the net driving the port does not have any other internal fanout by inserting an isolation cell. For an input port an isolation cell is inserted if the port is driving multiple cells or if the port is driving a pin of a cell that contains more than one input pin. By default, no action is taken if the above conditions are not met. If the **-force** option is specified, isolation is performed on the port even if these conditions are not met. If the type of isolation cell to be inserted is not specified, a buffer is inserted.

Note that bidirectional ports cannot be isolated using this command. In addition, no isolation is performed on a port by **compile** if the net connected to the port has a **dont_touch** attribute or if the port has been defined as a clock source.

Use **remove_isolate_ports** or **reset_design** to remove a port from the list of ports to be isolated. Use **report_isolate_ports** to list the isolation status of these ports.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example requests isolation on output port qout with a buffer.

```
prompt> set_isolate_ports -type buffer qout
```

The following command specifies isolation using a particular cell from the target library on an output port.

```
prompt> set_isolate_ports -driver IVDAP qout
```

SEE ALSO

```
remove_isolate_ports(2)  
report_isolate_ports(2)  
reset_design(2)
```

set_isolation

Defines the UPF isolation strategy for the power domains in the design. This command is supported only in UPF mode.

SYNTAX

```
status set_isolation
isolation_strategy
-domain power_domain
-isolation_power_net isolation_power_net
-isolation_ground_net isolation_ground_net
[-clamp_value 0 | 1 | z | latch]
[-applies_to inputs | outputs | both]
[-elements objects]
[-no_isolation]
```

Data Types

<i>isolation_strategy</i>	string
<i>power_domain</i>	string
<i>isolation_power_net</i>	string
<i>isolation_ground_net</i>	string
<i>objects</i>	list

ARGUMENTS

isolation_strategy
Specifies the UPF isolation strategy name. The isolation strategy name should be unique within the specified power domain.

-domain power_domain
Specifies the power domain name that this UPF isolation strategy will be applied to.

-isolation_power_net isolation_power_net
Specifies the isolation power net for the isolation cells that will be created based on this UPF isolation strategy.

-isolation_ground_net isolation_ground_net
Specifies the isolation ground net for the isolation cells that will be created based on this UPF isolation strategy. At least one of the **-isolation_power_net** or the **-isolation_ground_net** options should be specified if **-no_isolation** is not specified.

-clamp_value 0 | 1 | z | latch
Specifies the clamp value of the isolation cells that should be created based on this strategy. The default value for this option is 0.

-applies_to inputs | outputs | both
Specifies whether the given **set_isolation** command applies to all inputs or outputs or both kind of ports of the power domain. The default value for this option is **outputs**. This option cannot be used with the **-elements** option.

```
-elements objects
    Specifies the objects that this UPF isolation strategy will be applied to.
    The objects can be pins of the root cells of the power domain or ports of the
    top level design for top level power domains.

-no_isolation
    Specifies that elements under the influence of this set_isolation command
    should not be isolated.
```

DESCRIPTION

This command defines the UPF isolation strategy for the ports of the specified power domain.

If the **-elements** and **-applies_to** options are not specified, then the isolation strategy will be applied to all output ports of the power domain.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to define a UPF isolation strategy for all output ports of the specified power domain PD1. Power domain PD1 is defined on instance shutdown_inst.

```
prompt> set_isolation isolation_1 -domain PD1 \
-isolation_power_net PN1 -isolation_ground_net GN1
```

The following example shows how to define a UPF isolation strategy for specific ports of the specified power domain:

```
prompt> set_isolation isolation_2 -domain PD1 \
-isolation_power_net PN1 -isolation_ground_net GN1 \
-elements shutdown_inst/special_port
```

SEE ALSO

`set_isolation_control(2)`

set_isolation_control

Provides additional options needed for creating isolation cells. This command is needed with most **set_isolation** commands. This command is supported only in UPF mode.

SYNTAX

```
status set_isolation_control
isolation_strategy
-domain power_domain
-isolation_signal isolation_signal
[-isolation_sense low | high]
[-location self | parent]
```

Data Types

<i>isolation_strategy</i>	string
<i>power_domain</i>	string
<i>isolation_signal</i>	string

ARGUMENTS

isolation_strategy

Specifies the UPF isolation strategy name. The isolation strategy should already be defined in the specified power domain.
This argument is required.

-*domain power_domain*

Specifies the power domain name to which this UPF isolation strategy will be applied.
This option is required.

-*isolation_signal isolation_signal*

Specifies the isolation signal to use as the control signal of the isolation cells that should be created as a result of this isolation strategy. The *isolation_signal* can be a pin, port, or net.
This option is required.

-*isolation_sense low | high*

Specifies the isolation sense of the isolation cells that should be created as a result of this isolation strategy. The default value is high.

-*location self | parent*

Specifies the hierarchical location of the isolation cells that should be created as a result of this isolation strategy.
A value of self specifies that the isolation cell will be put in the hierarchy of the port being isolated. A value of parent specifies that isolation cells will be added in the parent hierarchy of the isolating port's hierarchy. The default value is self.

DESCRIPTION

This command applies to an existing isolation strategy specified by the **set_isolation** command. It provides extra parameters needed for creating isolation cells.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to define a UPF isolation strategy for all output ports of the specified power domain PD1. Power domain PD1 is defined on instance shutdown_inst, and isolation strategy isolation_1 is already defined.

```
prompt> set_isolation_control isolation_1 -domain PD1 \
           -location parent -isolation_signal en \
           -isolation_sense
```

SEE ALSO

`set_isolation(2)`

set_keepout_margin

Creates a keepout margin of the specified type for the specified cell or library cell.

SYNTAX

```
status set_keepout_margin
[-type hard | soft]
[-outer {lx by rx ty}]
[-tracks_per_macro_pin value]
[-min_padding_per_macro value]
[-max_padding_per_macro value]
[-all_macros]
[-macro_masters]
[-macro_instances]
[-north]
[object_list]
```

ARGUMENTS

-type hard | soft

Specifies the type of the keepout margin to be created. The value can be either soft or hard. If not specified hard will be taken as default value.

-outer {lx by rx ty}

Specifies the margin parameters for a keepout. lx, by, rx and ty represents the left, bottom, right, and top margins respectively. The margin parameters must be positive and all the four quantities are required. The unit for specification is micron. If the margins have been set on a standard cell instance or a standard cell master, for horizontal designs, only "lx" and "rx" will be honored; for vertical designs, only "by" and "ty" will be honored.

-tracks_per_macro_pin value

Specifies the number of tracks per macro pin. Default value is 0.5 tracks/pin. This will be used to calculate the pin count based derived keepout margin around macro cells. Pin count based derived keepout margin is always hard and -type will be ignored. -all_macros, -macro_masters, and -macro_instances are not allowed when we specify this option.

-min_padding_per_macro value

Specifies the min padding per macro size. Default value is min grid size which is 0. This will be used during the calculation of pin count based derived keepout margin and -type option will be ignored. -all_macros, -macro_masters and -macro_instances are not allowed when we specify this option. NOTE: During the derived keepout margin calculation of left and right side of the macro height of the cell will be taken into consideration and width of the cell for top and bottom.

-max_padding_per_macro value

Specifies the max padding per macro size. Default value is -1. This will be used during the calculation of pin count based derived keepout margin and -

type option will be ignored. -all_macros, -macro_masters and -macro_instances are not allowed when we specify this option. NOTE: During the derived keepout margin calculation of left and right side of the macro *height* of the cell will be taken into consideration and *width* of the cell for top and bottom.

-all_macros

Keepout margin of specified type will be created on all the macro cells of the design. Internally tool will find out the macro cells in the design.

-macro_masters

Keepout margin of the specified type will be created on all the macro masters or the macro masters of the macro instances specified in the object_list.

NOTE: If we specify this option, keepout margin will be created on only macro masters and tool will ignore all the standard cells and standard lib cells specified in the object_list.

-macro_instances

Keepout margin of the specified type will be created on all the macro instances or all the macro instances of the macro masters specified in the object_list. If we specify macro master in the object list tool will find out all the macro instances and creates the keepout margin on macro instances of the macro master. NOTE: If we specify this option, keepout margin will be created on only macro instances and tool will ignore all the standard cells and standard lib cells specified in the object_list.

-north

Specifies that given margin values are with respect to the north orientation of the cell.

object_list

Specifies the list of cells or library cells for which keepout margins are to be created.

DESCRIPTION

The **set_keepout_margin** command creates keepout margins for the specified cells and library cells. The tool will derive the keepout margins for the cells in the following order. 1. keepout margin specified on the cell itself 2. keepout margin specified on the lib cells of the cell 3. Pin count based derived keepout margin values in case of macro cells. NOTE: Please note that tool will derive pin count based keepout margin values only for the macro cells. If the tool does not find the keepout margin on the cell then it looks for the keepout margin specified on the lib cells. In case of macro cells if there is no user specified keepout margin on cells and lib cells then the tool looks for the pin count based derived keepout margin values. A keepout will be created for a cell or library cells whether or not the cell has a FIXED_PLACEMENT attribute. Keepout margins can be set on ILM cells and references also.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **set_keepout_margin** command.

```
prompt> set_keepout_margin -type hard \
      -outer {10 10 10 10} MY_CELL
prompt> set_keepout_margin -type hard \
      -outer {10 10 10 10} MY_LIB_CELL
```

This sets a keepout margin on the ILM reference blk.

```
prompt> set_keepout_margin -type hard \
      -outer {10 10 10 10} [get_ilms -reference blk]
```

This sets keepout margin on all the macro cells in the design.

```
prompt> set_keepout_margin -type hard -all_macros \
      -outer {10 10 10 10}
```

This sets a keepout margin on the basis of pin count of the macro.

```
prompt> set_keepout_margin -tracks_per_macro .6
      -min_padding_per_macro .1 -max_padding_per_macro 0.2
```

This sets a keepout margin on all the ILM instances in the design.

```
prompt> set_keepout_margin -type hard \
      -outer {10 10 10 10} [get_ilms]
```

SEE ALSO

`get_attribute(2)`
`remove_keepout_margin(2)`
`report_keepout_margin(2)`

set_latency_adjustment_options

Performs setting options for io latency adjustment.

SYNTAX

```
int set_latency_adjustment_options
[-from_clock clock_name]
[-to_clock collection_or_string_list]
[-exclude_clock collection_or_string_list]
[-latency float]
```

ARGUMENTS

-from_clock *clock_name*
Specify the clock from which the insertion delay (median arrival time among the sinks) will be applied to the real and/or virtual clocks in the **-to_clock** option.

-to_clock *collection_or_string_list*
Specify the list of real and /or virtual clocks whose latencies are to be updated based on either the latency from the **-from_clock** or the value from **-latency**.

-exclude_clock *collection_or_string_list*
Specify the list of clocks to be excluded from being updated.

-latency *float*
Specify the value to be used when clock latencies are being updated.

DESCRIPTION

The **set_latency_adjustment_options** command is used to set the stage for io latency adjustment after clock tree synthesis.

There are two basic modes of usage :

1. **set_latency_adjustment_options -from_clock clkA -to_clock {clkX clkY clkZ}**
2. **set_latency_adjustment_options -latency x.y -to_clock {clkM clkN clkJ}**

set_left_right_filler_rule

Sets left-right filler cell insertion rules.

SYNTAX

```
status set_left_right_filler_rule
-left
-right
-lib_cell
[-follow_stdcell_orientation]
```

ARGUMENTS

-left *left_filler*
Specify the filler cell that is to be inserted to the immediate left side of the standard cell in the *cell_list*.

-right *right_filler*
Specify the filler cell that is to be inserted to the immediate right side of the standard cell in the *cell_list*.

-lib_cell *cell_list*
cell_list must refers to a collection of cell references. The left-right filler cell insertion rule will be applied to the cells specified in this list.

DESCRIPTION

Use this command to set the left-right filler rules of the current design. A left (right) filler rule inserts a left (right) filler cell to the immediate left (right) side of a standard cell. A left or right filler cell is often used to avoid certain design rule spacing problems. The insertion of the left (right) filler cell is performed by the *insert_stdcell_filler* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies a filler rule that inserts "lf" on the left and "rf" on the right of library cells "cellA" and "cellB". The rule will be used in the *insert_stdcell_filler* command.

```
prompt> set_left_right_filler_rule -lib_cell {cellA, cellB} -left "lf" -right "rf"
```

set_left_right_filler_rule

2398

```
set_cell_vt_type(2)
remove_left_right_filler_rule(2)
report_left_right_filler_rule(2)
```

set_left_right_filler_rule
2399

set_level_shifter

Sets a strategy for level shifting during implementation. This command is supported only in UPF mode.

SYNTAX

```
status set_level_shifter
level_shifter_name
-domain domain_name
[-elements list]
[-applies_to inputs | outputs | both]
[-threshold value]
[-rule low_to_high | high_to_low | both]
[-location self | parent | fanout | automatic]
[-no_shift]
```

Data Types

level_shifter_name	string
domain_name	string
list	list
value	float

ARGUMENTS

level_shifter_name
Specifies the level shifter strategy name, which is used only for reporting.
This argument is required.

-domain domain_name
Specifies the domain for which the strategy is applied. This argument is required.

-elements list
Specifies a list of design elements, pins, or ports to which this strategy is applied.

-applies_to inputs | outputs | both
Specifies whether the domain's input ports, output ports, or both are level shifted. The default is both.

-threshold value
Specifies the voltage threshold (in volts) for determining when level shifters are required. The default is 0.

-rule low_to_high | high_to_low | both
Specifies which type of level shifters are required. The default is both.

-location self | parent | fanout | automatic
Specifies where the level shifter is placed in the logic hierarchy. The default is automatic.

```
-no_shift
    Prevents the insertion of level shifters on the specified ports, pins, and
    nets when used with the -elements option.
```

DESCRIPTION

The **set_level_shifter** command is used to set a strategy for level shifting during implementation. Level shifters are placed on the signals that have sources and sinks operating at different voltages, as their associated design elements are connected to different supply nets.

If a level shifter strategy is not specified on a power domain, the default level shifter strategy consists of all elements in the power domain, and uses the default strategy settings. Power state table (PST) and operating conditions are considered to determine if level shifters are needed for design elements on the boundaries of power domains.

If **-elements** list is specified, the elements must be in the domain specified by **-domain domain_name**.

The **-threshold** option defines how large the voltage difference between the driver and the sink needs to be before level shifters are inserted. Normally, this threshold value is determined from the cell libraries. Use the **-threshold** option to override the library values.

The **-rule** value can be `low_to_high`, `high_to_low`, or `both`.

- If `low_to_high` is specified, signals going from a lower voltage to a higher voltage get a level shifter when the voltage difference exceeds that specified by **-threshold**.
- If `high_to_low` is specified, signals going from a higher voltage to a lower voltage get a level shifter when the voltage difference exceeds that specified by **-threshold**.
- If `both` is specified, it is equivalent to having specified both rules in the strategy.

The **-location** option defines where the level shifter cells are placed in the logic hierarchy. All necessary supplies need to be available in the specified location. The option values are as follows:

- `self` specifies that the level shifter cell is placed inside the model or cell being shifted.
- `parent` specifies that the level shifter cell is placed in the parent of the cell or model being shifted.
- `fanout` specifies that the level shifter occurs at all fanout locations (sinks) of the port being shifted.
- `automatic` specifies that the implementation tool chooses the appropriate locations.

Note that this command does not apply to inout ports. Also, it is an error if the specified location is not within the logic design starting at the design root.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the level shifter strategy on PowerDomainZ:

```
prompt> set_level_shifter shift_up -domain PowerDomainZ -applies_to_outputs \
           -threshold 0.02 -rule both
```

SEE ALSO

add_port_state(2)
add_pst_state(2)
create_pst(2)
report_pst(2)

set_level_shifter_strategy

Sets the type of strategy to use for adjusting the voltage levels in the design.

SYNTAX

```
int set_level_shifter_strategy
    -rule all | low_to_high | high_to_low
    [-location inside | outside | source | sink]
```

ARGUMENTS

-rule all | low_to_high | high_to_low
Specifies to adjust the voltage levels when the operating voltage levels between a source and sink are different.
Using **-rule low_to_high** adjusts the voltage levels when a source at a higher voltage drives a sink at a lower voltage.
Using **-rule high_to_low** adjusts the voltage levels when a source at a lower voltage drives a sink at a higher voltage.
The **all** value is the default strategy.

-location inside | outside | source | sink
This option is only effective in power state table based level shifter insertion. It specifies the location for a level shifter when it is inserted on a boundary of two domains.
Using **-location inside** requires to place the level shifter in the inside domain of the two domains on the boundary.
Using **-location outside** requires to place the level shifter in the outside domain of the two domains on the boundary.
Using **-location source** requires to place the level shifter in the source domain of the two domains on the boundary.
Using **-location sink** requires to place the level shifter in the sink domain of the two domains on the boundary.
By default, the locations of inserted level shifters are automatically determined to avoid main power violation.

DESCRIPTION

This command specifies the strategy for level shifter insertion. The strategy defines the the level shifters insertion is to take place in the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the level shifter strategy to the **high_to_low** option:

```
prompt> set_level_shifter_strategy -rule high_to_low
```

SEE ALSO

`set_level_shifter_threshold(2)`

`set_level_shifter_strategy`
2404

set_level_shifter_threshold

Sets the minimum threshold beyond which the voltage adjustment is required.

SYNTAX

```
int set_level_shifter_threshold  
-voltage volt  
-percent diff
```

Data Types

<i>volt</i>	float
<i>diff</i>	float

ARGUMENTS

-voltage *volt*
The absolute difference between the source and sink voltages.

-percent *diff*
The percentage by which the source and sink voltages must differ. The percentage is determined as follows:

```
abs(driver(v)-load(v))/driver(v)*100
```

DESCRIPTION

This command specifies the minimum threshold value for the voltage difference between a source and a sink. Voltage values above the minimum threshold are adjusted. The threshold can be specified as the absolute difference in voltages or a percentage difference or both. If the **-voltage** and the **-percent** options are both specified, then either of the two thresholds be satisfied.

The default threshold voltage and percentage is zero.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the level shifter threshold value to the absolute difference of 0.5:

```
prompt> set_level_shifter_threshold -voltage 0.5
```

The following example sets the threshold value 5 percent:

```
prompt> set_level_shifter_threshold -percent 5
```

The following example sets the threshold value to 0.5 difference and 5 percent, so if either value is reached, the adjustment occurs:

```
prompt> set_level_shifter_threshold -voltage 0.5 -percent 5
```

SEE ALSO

`set_level_shifter_strategy(2)`

set_lib_attribute

Sets the value of an attribute on a library object.

SYNTAX

```
list set_lib_attribute
object_list
attribute_name
attribute_value
```

Data Types

object_list	list
attribute_name	string
attribute_value	datatype of attribute_name

ARGUMENTS

object_list	A list of the library objects on which the attribute is to be set.
attribute_name	The name of the attribute to set.
attribute_value	The value of the attribute. The datatype must be the same as that of the attribute.

DESCRIPTION

Sets the value of an attribute on a library object. Only the attribute values of a small set of library objects can be set using this command. For the complete list of such library objects and their related "updatable" attributes, please refer to the user manual.

This command returns the list of objects that have the specified attribute value set. A returned empty list means that the command was not successful.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This command is used to find the cell "INV" and set its area value to 1.0:

```
prompt> set_lib_attribute sample/INV area 1.0
Performing set_lib_attribute on library object 'sample/INV'.
```

```
{sample/INV}
```

In this example, an error is issued because the cell "INV1" is not found:

```
prompt> set_attribute sample/INV1 area 1.0
Error: The 'INV1' object does not exist in the 'sample' technology library
. (UIL-54)
{}
```

In the following command, the "lib_udg_attr" value for the user-defined group "lib_udg1" in the library "sample" is set to "test":

```
prompt> set_lib_attribute sample/lib_udg1 lib_udg_attr test
Performing set_lib_attribute on library object 'sample/lib_udg1'.
{sample/lib_udg1}
```

In the following command, the area values for gates "G1" and "G2" in the library "tech_lib" are both set to 2.0:

```
prompt> get_lib_attribute {sample/G1, sample/G2} area
Performing set_lib_attribute on library object 'sample/G1'.
Performing set_lib_attribute on library object 'sample/G2'.
{"sample/G1", "sample/G2"}
```

SEE ALSO

`get_attribute(2)`

set_lib_cell_spacing_label

Sets an intercell-spacing constraint label on a reference cell.

SYNTAX

```
status set_lib_cell_spacing_label
-names {list_of_label_names}
[-left_lib_cells {lib_cell_collection}]
[-right_lib_cells {lib_cell_collection}]
```

Data Types

<i>list_of_label_names</i>	list of strings
<i>lib_cell_collection</i>	collection

ARGUMENTS

```
-names {list_of_label_names}
      Lists intercell constraint labels to assign to one or more reference cell.

-left_lib_cells {lib_cell_collection}
      Specifies collection of reference cells that have the given labels assigned
      to the left side of the cell in the "North" orientation.

-right_lib_cells {lib_cell_collection}
      Specifies collection of reference cells that have the given labels assigned
      to the right side of the cell in the "North" orientation.
```

DESCRIPTION

This command assigns labels to a collection of reference (library) cells in order to enable the legalization tool to obey intercell spacing constraints. A label is a string assigned by the user to the left and/or right of a standard cell. This command works in concert with the command set_spacing_label_rule that defines the range of spacing between two adjacent labels that is illegal. All spacing rules specified by set_spacing_label_rule commands need to be satisfied to produce a legal placement. With intercell spacing rule specified, it is no longer assumed that any two standard cells can be placed next to each other with a certain spacing.

The labels and spacing rules can be used to express spacing requirements that originate from mask rules and the layout of standard cells. The labels and spacing rules are stored in the library and will be applied to all designs of the library once specified.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, reference cells AND* are assigned label "X" on the left of the cell in the "North" orientation, and reference cells NAND* are assigned label "X" on the right.

```
prompt> set_lib_cell_spacing_label -names {X}\
-left_lib_cells {AND*}\
-right_lib_cells {NAND*}
```

In the following example, reference cell OR2X4 is assigned labels "Y" and "Z" on the right side.

```
prompt> set_lib_cell_spacing_label\
-names {Y Z} -right_lib_cells {OR2X4}
```

SEE ALSO

```
remove_all_spacing_rules(2)
report_spacing_rules(2)
set_spacing_label_rule(2)
```

set_load

Sets the **load** attribute to a specified value on specified ports and nets.

SYNTAX

```
status set_load
value
objects
[-subtract_pin_load]
[-min]
[-max]
[[-pin_load] [-wire_load]]
```

Data Types

value	float
objects	list

ARGUMENTS

value

Specifies the value with which to set the **load** attribute on the ports and nets contained in *objects*. The *value* must be expressed in units consistent with the technology library used during optimization. For example, if the technology library specifies load values in picofarads, *value* must also be expressed in picofarads.

objects

Specifies a list of ports and nets in the current design whose loads are to be set.

-subtract_pin_load

Indicates that the current pin capacitances of the net are to be subtracted from *value* before the net load value is set. If the resulting net load value is negative, it is set to 0. This option sets the **subtract_pin_load** attribute on *objects*. With this attribute set, the total load computed on these nets during **update_timing** does not include pin loads. Use this option if *value* includes pins and ports capacitances. The **subtract_pin_load** attribute is not placed on ports.

-min

Indicates that the load value is to be used for minimum delay analysis. You cannot use the legacy option **-fanout_number** with **-min**, because different fanout numbers for min and max are not supported. If no minimum load value is specified, the maximum value is used.

-max

Indicates that the load value is to be used for maximum delay analysis. If no value is specified for maximum analysis on a net, and a value has been specified for minimum analysis, the minimum value is ignored. (You cannot annotate only a minimum value on a net.)

```
-pin_load -wire_load
    Indicates whether the specified value on the port is to be treated as a pin
    load, as a wire load, or as both. These options can be used only with ports;
    an error message is displayed if the objects contains any nets. If you do not
    specify either -pin_load or -wire_load, -pin_load is used as the default. You
    can use both arguments together, in which case the load value is set as both
    a pin load and as a wire load on the specified ports.
```

DESCRIPTION

This command sets the **load** attribute on ports and nets in the current design. If the current design is hierarchical, it must have been linked with the **link** command. The total load on a net is the sum of all of pin loads, port loads, and wire loads associated with that net. The specified value overrides the internally-estimated net load value.

You also can use the **set_load** command for nets at lower levels of the design hierarchy. These nets are specified as BLOCK1/BLOCK2/NET_NAME.

If you use the **-wire_load** option, value is set as a wire load on the specified port. However, the value is actually counted as part of the total wire load and not as part of the pin or port load.

To view load values on ports, use the **report_port** command. To view load values on nets, use the **report_net** or **report_internal_loads** command.

To reset a load value, use the **remove_attribute** command. To reset all annotated load values in a design, use the **reset_design** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets a load of 2 units to the port named the_answer:

```
prompt> set_load 2 the_answer
```

The following example sets a load of 2.5 units (the estimated wire load) plus the load of 3 inverter input pins from the tech_lib library on all output ports. The user-defined dc_shell variable **port_load** is used to store this load value.

```
prompt> link -all
prompt> port_load = 2.5 + 3 * load_of(tech_lib/IV/A)
prompt> set_load port_load all_outputs()
```

The following example sets a load of pin Z of IV from the tech_lib library to the

input_1 and input_2 ports, using the **load_of** command:

```
prompt> set_load load_of(tech_lib/IV/Z) {input_1 input_2}
```

In the following example, a load of 3 is set on the U1/U2/NET3 net. The wire capacitance is set to 3. (Total net capacitance is 3 plus the sum of the pin and port capacitances.)

```
prompt> set_load 3 U1/U2/NET3
```

In the following example, a total net capacitance (wire capacitance plus pin capacitances) of 3 is set on the U1/U2/NET3 net. If the pin and port capacitances equal 2, the wire capacitance is annotated with 1. If the pin and port capacitances are 3 or more, the wire capacitance is annotated with 0.

```
prompt> set_load -subtract_pin_load 3 U1/U2/NET3
```

The following example sets a wire load of 5 units on the port named the_answer:

```
prompt> set_load -wire_load 5 the_answer
```

The following sequence of commands describes the external fanout of an output port:

```
prompt> set_load -fanout_number 5 [get_ports O1]
```

```
prompt> set_wire_load_model -port_list [get_ports O1] "default_wl"
```

The following commands remove the back-annotated load on a port and on a net:

```
prompt> remove_attribute [get_ports the_answer] load
```

```
prompt> remove_attribute [get_ports the_answer] "wire_capacitance"
```

```
prompt> remove_attribute [get_ports O1] "fanout_number"
```

```
prompt> remove_attribute [get_nets U1/U2/NET3] load
```

set_local_link_library

Sets the **local_link_library** attribute to specified files and libraries on the current design.

SYNTAX

```
int set_local_link_library  
local_link_library
```

Data Types

local_link_library string

ARGUMENTS

local_link_library

Specifies a list of files with which the **local_link_library** attribute is to be set on the current design. The **local_link_library** files are not loaded or checked until the **link_library** is used.

DESCRIPTION

Sets the **local_link_library** attribute to *local_link_library* on the current design. The *local_link_library* is a list of design files and libraries that is added to the beginning of the **link_library** whenever a link operation is performed. Files in the *local_link_library* are searched first.

The **compile**, **insert_dft**, and **translate** commands set this attribute to the same value as the **target_library** variable.

Use **report_design** or **get_attribute** to identify the **local_link_library** for a design.

To remove this attribute, use the **remove_attribute** or **reset_design** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command sets the **local_link_library** "tech_lib.db" on the current design "my_design":

```
prompt> set_local_link_library tech_lib.db  
Setting local link library 'tech_lib.db' on design 'my_design'
```

SEE ALSO

`current_design(2)`

`remove_attribute(2)`
`reset_design(2)`
`link_library(3)`
`target_library(3)`

set_logic_dc

Specifies one or more input ports in the current design that are to be driven by don't care. The **set_logic_one** and **set_logic_zero** commands are used the same way as this command.

SYNTAX

```
int set_logic_dc  
port_list
```

Data Types

port_list list

ARGUMENTS

port_list

A list of input port names in the current design that are to be driven by don't care. You can use only one of **set_logic_one**, **set_logic_zero**, or **set_logic_dc** on any given port. If you specify more than one port, you must include them in braces ({}).

DESCRIPTION

Assigns a **driven_by_dont-care** attribute to the ports in *port_list*; a given port can have only one of the **driven_by_logic_one**, **driven_by_logic_zero**, and **driven_by_dont-care** attributes. This information is used by **compile** to create smaller designs by eliminating logic that is tied to a specific value and therefore might not need to be maintained during optimization. After optimization, a port connected to logic one, logic zero, or don't care usually does not drive anything inside the optimized design.

Note: This command cannot be used on output ports. To specify output ports as unconnected, use the **set_unconnected** command.

When a **set_logic_dc** command is used on an input port, **compile** is given the freedom to assign any signal to that input (including, but not limited to, zero and one). The meaning of this command is that the outputs of the design are significant only when the non-don't care inputs completely determine all outputs, independent of the don't care inputs. This information is used to optimize the design.

For example, suppose the design is a 2:1 multiplexer with inputs S, A, B, and output Z. The function computed is as follows:

```
Z = S*A + S'*B
```

If you issue the following command,

```
prompt> set_logic_dc B
```

the implication is that the value of Z is significant only when S=1, and is a don't

care when S=0. The resulting simplification done by **compile** represents the reduced logic as a wire, and the function is as follows:

```
Z = A
```

Use the **remove_attribute** command to remove these attributes.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following commands are issued to drive input ports "A" and "B" by logic 0, input port "C" by logic 1, and input port "D" by don't care:

```
prompt> set_logic_zero {A B}
prompt> set_logic_one C
prompt> set_logic_dc D
```

SEE ALSO

```

set_logic_zero(2)
set_unconnected(2)
```

set_logic_one

Specifies one or more input ports in the current design that are to be driven by logic one. The **set_logic_zero** and **set_logic_dc** commands are used the same way as this command.

SYNTAX

```
int set_logic_one  
port_list
```

Data Types

port_list list

ARGUMENTS

port_list

A list of input port names in the current design that are to be driven by logic one. You can use only one of **set_logic_one**, **set_logic_zero**, or **set_logic_dc** on any given port. If you specify more than one port, you must include them in braces ({}).

DESCRIPTION

Assigns a **driven_by_logic_one** attribute to the ports in *port_list*; a given port can have only one of the **driven_by_logic_one**, **driven_by_logic_zero**, and **driven_by_dont-care** attributes. This information is used by **compile** to create smaller designs by eliminating logic that is tied to a specific value and therefore might not need to be maintained during optimization. After optimization, a port connected to logic one, logic zero, or don't care usually does not drive anything inside the optimized design.

Note: This command cannot be used on output ports. To specify output ports as unconnected, use the **set_unconnected** command.

Use the **remove_attribute** command to remove these attributes.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following commands are issued to drive input ports "A" and "B" by logic 0, input port "C" by logic 1, and input port "D" by don't care:

```
prompt> set_logic_zero {A B}  
prompt> set_logic_one C
```

```
prompt> set_logic_dc D
```

SEE ALSO

```
get_attribute(2)
remove_attribute(2)
reset_design(2)
set_logic_dc(2)
set_logic_zero(2)
set_unconnected(2)
```

set_logic_zero

Specifies one or more input ports in the current design that are to be driven by logic zero. The **set_logic_one** and **set_logic_dc** commands are used the same way as this command.

SYNTAX

```
int set_logic_zero  
port_list
```

Data Types

port_list list

ARGUMENTS

port_list

A list of input port names in the current design that are to be driven by logic zero. You can use only one of **set_logic_one**, **set_logic_zero**, or **set_logic_dc** on any given port. If you specify more than one port, you must include them in braces ({}).

DESCRIPTION

Assigns a **driven_by_logic_zero** attribute to the ports in *port_list*; a given port can have only one of the **driven_by_logic_one**, **driven_by_logic_zero**, and **driven_by_dont-care** attributes. This information is used by **compile** to create smaller designs by eliminating logic that is tied to a specific value and therefore might not need to be maintained during optimization. After optimization, a port connected to logic one, logic zero, or don't care usually does not drive anything inside the optimized design.

Note: This command cannot be used on output ports. To specify output ports as unconnected, use the **set_unconnected** command.

Use the **remove_attribute** command to remove these attributes.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following commands are issued to drive input ports "A" and "B" by logic 0, input port "C" by logic 1, and input port "D" by don't care:

```
prompt> set_logic_zero {A B}  
prompt> set_logic_one C
```

```
prompt> set_logic_dc D
```

SEE ALSO

set_logic_dc(2)
set_logic_one(2)
set_unconnected(2)
```

set_macro_cell_bound_spot

Updates the macro cell move bound or group bound by specifying the exact location (spot) for the bound inside the macro cell.

SYNTAX

```
status set_macro_cell_bound_spot
macro_cell_object
-coordinates {spot_x spot_y}
```

Data Types

<i>macro_cell_object</i>	string
<i>spot_x</i>	float
<i>spot_y</i>	float

ARGUMENTS

macro_cell_object

Specifies the macro cell that is related to a move bound or group bound.

-coordinates {*spot_x* *spot_y*}

Uses {*spot_x* *spot_y*} to specify the x and y coordinates of the location for the bound inside the macro cell. Note that {*spot_x* *spot_y*} are related to the physical library cell of the macro cell (that is, they are based on the library cell origin without cell rotation). The move bound or group bound related to this macro cell tries to bound the other standard cells to this exact location in the macro cell.

DESCRIPTION

This command specifies a location (or spot) inside the macro cell so that tools bound the standard cell to this exact point in the macro cell. Without this capability, the placer places the standard cell at any location in the macro cell. This can cause poor quality of results (QoR) if the standard cell is placed on the wrong side of the macro cell.

You can also use the **create_bounds** or **update_bounds** command to directly specify the macro cell pin so that the first pin geometry in the macro cell is assigned as the location in it to which standard cells are bound.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to bound the standard cell Top/U1 to the macro cell Top/RAM16x16 at the exact location {10.5 20.2}, related to its physical library cell

```
set_macro_cell_bound_spot
```

```
2422
```

origin.

```
prompt> create_bounds\
-coord {0 0 100 100} {Top/U1 Top/RAM16x16
prompt> set_macro_cell_bound_spot\
-coord {10.5 20.2} [get_cell "Top/RAM16x16"]fp
```

The following example shows the use of the command given the description below. If the CLK pin in the RAM16x16 macro cell is the one that must bound with the standard cell U1, the following command directly bounds the CLK pin inside the Top/RAM16x16 cell to the Top/U1 standard cell. However, the placer picks the first CLK port geometry in the physical library cell of the macro and assigns it as the location (spot) in the macro cell. It might or might not be {10.5 20.2}, depending on how many geometries for the CLK port are in the physical library cell.

```
prompt> create_bounds\
-coord {0 0 100 100} {Top/U1 Top/RAM16x16/CLK
```

SEE ALSO

```
create_bounds(2)
get_bounds(2)
update_bounds(2)
report_bounds(2)
```

set_max_area

Sets the **max_area** attribute to a specified value on the current design.

SYNTAX

```
int set_max_area  
[-ignore_tns]  
area_value
```

Data Types

```
area_value      float
```

ARGUMENTS

-ignore_tns

Specifies that the area is prioritized above total negative slack (TNS).

area_value

Specifies the value to which the **max_area** attribute is to be set. The units of **area** must be consistent with the units in the technology library used during optimization.

DESCRIPTION

This command sets the **max_area** attribute to **area** on the current design. The **max_area** attribute represents the target area of the design and is used by the **compile** command to calculate area cost of the design.

By default, **compile** prioritizes total negative slack (TNS) above area. This means that **compile** does not create new delay violations or worsen existing delay violations on a path that has negative delay slack in order to improve area.

When the **-ignore_tns** option is used, the **ignore_tns** attribute is set on the design. When this attribute is set, **compile** prioritizes area above TNS. This means that **compile** may increase delay violations at an endpoint in order to improve area, as long as the new delay violation is smaller than the delay violation on the endpoint of the most critical path in the same path group.

If you specify **max_area** more than once on a design, the most recent **area** is used and the earlier values are removed.

If the **set_max_area** command is used without the **-ignore_tns** option, then the **ignore_tns** attribute (if any) on the design is deleted.

To undo **set_max_area**, use the **remove_attribute** or **reset_design** command.

Use the **report_area** command to get a detailed summary of area of the design. Use the **report_constraint** command to show area cost of the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the target area for the current design to 0.0 (zero). This causes **compile** to create a design that has been optimized for the smallest possible size.

```
prompt> set_max_area 0.0
```

SEE ALSO

```
current_design(2)
remove_attribute(2)
report_area(2)
report_constraint(2)
reset_design(2)
```

set_max_capacitance

Sets the **max_capacitance** attribute to a specified value on the specified input ports and designs.

SYNTAX

```
int set_max_capacitance  
capacitance_value  
object_list
```

ARGUMENTS

capacitance_value

Specifies a value to which the **max_capacitance** attribute is to be set. *capacitance_value* must be expressed in units consistent with the technology library used during optimization. For example, if the library specifies capacitance values in picofarads, then *capacitance_value* must also be expressed in picofarads.

object_list

Specifies a list of names of input ports and/or designs on which the **max_capacitance** attribute is to be set.

DESCRIPTION

Sets the **max_capacitance** attribute to *capacitance_value* on the specified input ports or designs. **compile** attempts to ensure that the capacitance value for a net is less than *capacitance_value*. The maximum capacitance value for a net is defined as the least of the maximum capacitance values of the cell pins and design ports on that net.

In cases where both a global maximum capacitance value is set on a design and a local value is set on a port, **compile** attempts to meet the smaller (more restrictive) value.

If **max_capacitance** attributes are already specified in a technology library (implicit constraints), **compile** automatically tries to meet them.

By default, a port or design has no **max_capacitance** constraint.

Please note that by this command **max_capacitance** attribute can not be set on output or bidirectional port.

max_capacitance, along with **max_fanout** and **max_transition**, is a *design rule constraint*; **max_delay** and **max_area** are optimization constraints. Design rule constraints reflect those technology-specific restrictions that *must* be met for a design to function correctly, while optimization constraints reflect goals and restrictions that are desirable, but not crucial for the operation of a design. Design Compiler attempts to meet all constraints placed on a design, but gives priority to design rule constraints in the optimization process. Therefore, **compile** gives preference to **max_capacitance** and other design rule constraints, even if they

adversely affect optimization constraints on a design.

To get information about optimization and design rule constraints, use **report_constraint**; to get information on the current port settings, use **report_port**. To remove the **max_capacitance** attribute from a port or a design, use **remove_attribute**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets a maximum capacitance value of 2.0 units on the port named "late_riser":

```
prompt> set_max_capacitance 2.0 late_riser
```

The following example specifies a maximum capacitance value of 2.0 units for the design "TEST":

```
prompt> set_max_capacitance 2.0 TEST
```

set_max_delay

Specifies a maximum delay target for paths in the current design.

SYNTAX

```
int set_max_delay
delay_value
[-rise | -fall]
[-from from_list
 | -rise_from rise_from_list
 | -fall_from fall_from_list]
[-through through_list]
[-rise_through rise_through_list]
[-fall_through fall_through_list]
[-to to_list
 | -rise_to rise_to_list
 | -fall_to fall_to_list]
[-group_path group_name]
[-reset_path]
```

Data Types

delay_value	float
from_list	list
rise_from_list	list
fall_from_list	list
through_list	list
rise_through_list	list
fall_through_list	list
to_list	list
rise_to_list	list
fall_to_list	list
group_name	string

ARGUMENTS

delay_value

Specifies the value of the desired maximum delay for paths between start and end points. You must express *delay_value* in the same units as the technology library used during optimization. If a path startpoint is on a sequential device, clock skew is included in the computed delay. If a path startpoint has an input delay specified, that delay value is added to the path delay. If a path endpoint is on a sequential device, clock skew and library setup time are included in the computed delay. If the endpoint has an output delay specified, that delay is added into the path delay.

-rise | -fall

Specifies whether endpoint rising or falling delays are constrained. If you don't specify either, both rising and falling delays are constrained.

-from from_list

Specifies a list of path startpoints (port, pin, clock, or cell names) of the

set_max_delay

2428

current design. If you specify a clock, all path startpoints related to that clock are affected. If you specify a cell name, one path startpoint on that cell is affected. All paths from these startpoints to the endpoints in the *to_list* are constrained to *delay_value*. If you don't specify *to_list*, all paths from *from_list* are affected. This list cannot include output ports. If you include more than one object, you must enclose the objects in quotation marks ("") or braces ({}).

`-rise_from rise_from_list`

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

`-fall_from fall_from_list`

Same as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

`-through through_list`

Determines a list of path throughpoints (port, pin, or leaf cell names) of the current design. The max delay value applies only to paths that pass through one of the points in the *through_list*. If you include more than one object, you must enclose the objects in quotation marks ("") or braces ({}). If you specify the **-through** option multiple times, the max delay values apply to paths that pass through a member of each *through_list* in the order in which the lists were given. In other words, the path must first pass through a member of the first *through_list*, then through a member of the second list, and so on, for every through list specified. If you use the **-through** option in combination with the **-from** or **-to** option, max delay applies only if the **-from** or **-to** conditions are satisfied and the **-through** conditions are satisfied.

`-rise_through rise_through_list`

Same as the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than once in a single command invocation as with the **-through** option.

`-fall_through fall_through_list`

Same as the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than once in a single command invocation as with the **-through** option.

`-to to_list`

Specifies a list of path endpoints (port, clock, cell, or pin names) of the current design. All paths to the endpoints in the *to_list* are constrained to *delay_value*. If you don't specify a *from_list*, all paths to *to_list* are affected. This list cannot include input ports. If you include more than one object, you must enclose the objects in quotation marks ("") or braces ({}). If you specify a cell, one path endpoint on that cell is affected. If you specify a clock, all path endpoints related to that clock are affected.

```

-rise_to rise_to_list
    Same as the -to option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of -to, -rise_to, and -fall_to.
-fall_to fall_to_list
    Same as the -to option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of -to, -rise_to, and -fall_to.
-group_path group_name
    Specifies the name of the group to which the paths are to be added. If the group does not already exist, it is created. This is equivalent to separately specifying the group_path command with the -name group_name -from from_list -to to_list options in addition to specifying the set_max_delay command. If you do not specify this option, the existing path grouping is not changed.
-reset_path
    Removes existing point-to-point exception information on the specified paths. Only information of the same rise/fall setup/hold type is reset. This is equivalent to using the reset_path command with similar options before executing the set_max_delay command.

```

DESCRIPTION

Specifies the desired maximum delay for paths in the current design. This command specifies that the maximum path length for any startpoint in *from_list* to any endpoint in *to_list* must be less than *delay_value*.

Individual maximum delay targets are automatically derived from clock waveforms and port input or output delays. For more information, see the **create_clock**, **set_input_delay**, and **set_output_delay** man pages.

The optimization cost of the design depends on how path groups have been specified. For more information, see the **group_path** man page.

The **set_max_delay** command is a point-to-point timing exception command; that is, it overrides the default single-cycle timing relationship for one or more timing paths. Other point-to-point timing exception commands include the **set_multicycle_path**, **set_min_delay**, and **set_false_path** commands.

If a path satisfies multiple timing exceptions, the following rules are applied to determine which exceptions take effect. Rules referring to **-from** apply equally to **-rise_from** and **-fall_from**, and similarly for the rise and fall options of **-through** and **-to**.

1. Two **group_path** commands can conflict with each other. But a **group_path** exception by itself does not conflict with another type of exception. Thus, the remaining rules apply for two **group_path** exceptions or two non-**group_path** exceptions.

2. If both exceptions are **set_false_paths**, no conflict occurs.
3. If one exception is a **set_max_delay** and the other is a **set_min_delay**, no conflict occurs.
4. If one exception is a **set_multicycle_path -hold** and the other is **set_multicycle_path -setup**, no conflict occurs.
5. If one exception is a **set_false_path** and the other is not, the **set_false_path** takes precedence.
6. If one exception is a **set_max_delay** and the other is not, the **set_max_delay** takes precedence.
7. If one exception is a **set_min_delay** and the other is not, the **set_min_delay** takes precedence.
8. If one exception has a -from pin or -from cell and the other does not, the former takes precedence.
9. If one exception has a -to pin or -to cell and the other does not, the former takes precedence.
10. If one exception has any -through points and the other does not, the former takes precedence.
11. If one exception has a -from clock and the other does not, the former takes precedence.
12. If one exception has a -to clock and the other does not, the former takes precedence.
13. The exception with the more restrictive constraint then takes precedence. For **set_max_delay** and **set_multicycle_path -setup**, this is the constraint with the lower value. For **set_min_delay** and **set_multicycle_path -hold**, it is the constraint with the higher value.

The value of a **max_rise_delay** attribute cannot be less than that of a **min_rise_delay** attribute on the same path (and similarly for fall attributes). If this occurs, the old attribute is removed.

Note: Specifying a **min_delay** or **max_delay** to a pin that is not a path endpoint places an implicit **dont_touch** attribute on that cell.

The **-group_path** option modifies the path grouping. Path grouping affects the maximum delay cost function. The worst violator within each group adds to the cost. For optimization, grouping some paths separately can improve their delay cost, but it might also increase design area, and compile time.

Use the **report_timing_requirements** command to list the **max_delay**, **min_delay**, **multicycle_path**, and **false_path** information for the design. Use **report_path_group** to list the path groups which are defined.

To undo **set_max_delay**, use **reset_path**.

To modify paths grouped with the **-group_path** option, use the **group_path** command to place the paths in another group or the default group.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows how to optimize the design so that any delay path to a port named Y is less than 10 units.

```
prompt> set_max_delay 10.0 -to {Y}
```

This example shows how to specify that all paths from ff1a or ff1b that pass through cell u1 and end at ff2e must be less than 15.0 units.

```
prompt> set_max_delay 15.0 -from {ff1a ff1b} -through {u1} -to {ff2e}
```

example shows how to specify that all paths to endpoints clocked by PHI2 must be less than 8.5 units.

```
prompt> set_max_delay 8.5 -to [get_clocks PHI2]
```

This example shows how to set a requirement that all paths leading to ports named busA[*] have a delay of less than 5.0 and are included in the path group named busA.

```
prompt> set_max_delay 5.0 -to "busA[*]" -group_path "busA"
```

This example shows how to set a maximum delay requirement of 3.0 for all paths that first pass through either u1/Z or u2/Z then pass through u5/Z or u6/Z.

```
prompt> set_max_delay 3.0 -through {u1/Z u2/Z} -through {u5/Z u6/Z}
```

This example specifies that all timing paths from ff1/CP to ff2/D that rise through one or more of {U1/Z U2/Z} and fall through one or more of {U3/Z U4/C} must have delays less than 8.0 units.

```
prompt> set_max_delay 8.0 -from {ff1/CP} -rise_through {U1/Z U2/Z} -  
fall_through {U3/Z U4/C} -to {ff2/D}
```

set_max_dynamic_power

Sets the target dynamic power for the current design by setting the **max_dynamic_power** attribute to a specified value.

SYNTAX

```
int set_max_dynamic_power
dynamic_power
[GW | MW | KW | W | mW | uW | nW | pW | fW | aW]
```

Data Types

dynamic_power float

ARGUMENTS

dynamic_power

Specifies the maximum target dynamic power of the current design; that is, the value to which the **max_dynamic_power** attribute is to be set.

GW | MW | KW | W | mW | uW | nW | pW | fW | aW

Specifies the power dimension. If not specified, then the units of *dynamic_power* are assumed to be the same as those in the technology library used during optimization.

DESCRIPTION

Sets the target (desired) dynamic power for the current design by setting the **max_dynamic_power** attribute. **max_dynamic_power** is set to a value no greater than *dynamic_power*. If **max_dynamic_power** is set more than once for a design, the last value is used.

To remove the **max_dynamic_power** attribute, use **remove_attribute** or **reset_design**.

To get information about the dynamic power usage of the current design, use **report_power**. To list the power cost of the design, use **report_constraint**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets the target dynamic power to zero for the current design.

```
prompt> set_max_dynamic_power 0.0
```

SEE ALSO

`current_design(2)`
`remove_attribute(2)`
`report_constraint(2)`
`report_power(2)`
`reset_design(2)`

set_max_fanout

Sets the **max_fanout** attribute to a specified value on specified input ports and/or designs.

SYNTAX

```
int set_max_fanout  
fanout_value  
object_list
```

ARGUMENTS

fanout_value
Specifies the value to which the **max_fanout** attribute is to be set; that is, the maximum fanout value.

object_list
Specifies a list of input ports and/or designs on which the **max_fanout** attribute is to be set.

DESCRIPTION

Sets the **max_fanout** attribute on the specified input ports and/or designs. **compile** attempts to ensure that the sum of the **fanout_load** attributes for input pins on nets driven by the specified ports or all nets in the specified design is less than the given value. There is no maximum value placed by default, but if there is a **max_fanout** attribute already specified in a technology library (an implicit constraint), **compile** attempts to meet it.

In cases where both a global fanout limit is set on a design, and a local value is set on a port, **compile** attempts to meet the smaller (more restrictive) value.

In general, design rule constraints reflect technology-specific constraints that *must* be met for a design to function correctly. Optimization constraints are design goals and restrictions that are desirable but not crucial for the operation of a design. **compile** attempts to meet all constraints placed on a design, but it gives priority to design rule constraints in the optimization process.

The **max_fanout** attribute specifies Maximum Fanout, a *design rule constraint*. Thus, **compile** gives precedence to fixing a **max_fanout** violation, even if it adversely affects *optimization constraints* (for example, Maximum Delay and Maximum Area).

Use **report_constraint** to get information about optimization and design rule constraints.

To remove a maximum fanout from a port or design, use **remove_attribute**. **reset_design** removes all attributes, including **max_fanout**, from the current design.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets a maximum fanout of 20.0 units on the port "going_places":

```
prompt> set_max_fanout 20.0 going_places
```

In the following example, the **max_fanout** attribute is set to 18.5 on the design "TEST":

```
prompt> set_max_fanout 18.5 TEST
```

set_max_leakage_power

Sets the target leakage power for the current design by setting the **max_leakage_power** attribute to a specified value.

SYNTAX

```
int set_max_leakage_power  
leakage_power  
[GW | MW | KW | W | mW | uW | nW | pW | fW | aW]
```

Data Types

leakage_power float

ARGUMENTS

leakage_power
Specifies the target leakage power of the current design; that is, the value to which the **max_leakage_power** attribute is to be set.

[GW | MW | KW | W | mW | uW | nW | pW | fW | aW]
Specifies the power dimension. If not specified, then the units of *leakage_power* are assumed to be the same as those in the technology library used during optimization.

DESCRIPTION

Sets the target (desired) leakage power of the current design by setting the **max_leakage_power** attribute. **max_leakage_power** is set to a value no greater than *leakage_power*. If **max_leakage_power** is set more than once for a design, the latest value is used.

To remove the **max_leakage_power** attribute, use **remove_attribute** or **reset_design**.

To get information about the leakage power usage of the current design, use **report_power**. To list the power cost of the design, use **report_constraint**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets the target power to zero for the current design.

```
prompt> set_max_leakage_power 0.0
```

SEE ALSO

`current_design(2)`
`remove_attribute(2)`
`report_constraint(2)`
`report_power(2)`

set_max_lvth_percentage

Sets the the maximum percentage of the total cell area that can be of a low threshold voltage group.

SYNTAX

```
status set_max_lvth_percentage
[max_lvth]
[-lvth_groups groups]
[-reset]
```

Data Types

<i>max_lvth</i>	float
<i>groups</i>	string list

ARGUMENTS

max_lvth

Specifies the max %lvth area constraint value to be set on the current design. The constraint value is a floating point number representing a percentage value between 0 and 100.

-lvth_groups groups

Specifies the list of vth groups to be considered as low vth. The value of the *groups* argument is a list of vth group identifiers. Each identifier is a non-empty string that may consist of alphanumeric characters and the underscore character ("_").

-reset

Removes the max %lvth constraint from the current design.

DESCRIPTION

The **set_max_lvth_percentage** command sets a max %lvth area constraint on the current design and specifies which vth groups are considered as low vth. The max %lvth area constraint specifies the maximum percentage of the total cell area that can be of a low voltage threshold (low vth) group.

The vth group of a cell is defined as the vth group of its library cell; the vth group of a library cell is defined by the value of the library cell level `threshold_voltage_group` attribute or the library level `default_threshold_voltage_group` attribute. If a design contains cells belonging to the vth groups: lvt, xlvt, svt and hvt; and if lvt and xlvt are considered as the low vth groups, then the %lvth area of the design is the ratio (represented as a percentage value) of the cell area of the cells belonging to the lvt or xlvt groups with respect to the total cell area of the design.

The max %lvth area constraint is an upperbound to the %lvth area of the design. The constraint value is specified as the floating point argument of the **set_max_lvth_percentage** command. The list of vth groups that are to be considered as

low vth is specified using the **-lvth_groups** argument. The **-reset** can be used to remove the current max %lvth constraint. The command can be issued without any arguments to display the current %lvth constraint set on the design.

In Design Compiler, the %lvth constraint is only honored by **compile_ultra** during leakage power optimization, that is, when the **max_leakage_power** constraint is also set. In IC Compiler, the constraint will be triggered with -power switch of mega commands (place_opt/clock_opt/route_opt) and atomic (psynopt) command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows how to set the max %lvth area constraint on the current design.

```
prompt> set_max_lvth_percentage -lvth_groups {xlvt lvt} 20.0
```

In this case the %lvth constraint information specifies that the total area of the cells with vth groups xlvt and lvt can be 20% of the total design area. For example, if 10% of the cell area is of vth group xlvt and 5% is of vth group lvt, then the constraint is satisfied since 15% of the cell area is considered to be low vth. On the other hand, if 15% of the cell area is xlvt and 10% is lvt then the constraint is not met (25% of the cell area is low vth).

The following example removes the current max %lvth constraint.

```
prompt> set_max_lvth_percentage -reset
```

SEE ALSO

`set_max_leakage_power(2)`

set_max_net_length

Sets the **max_net_length** attribute to a specified value on specified input ports and/or designs.

SYNTAX

```
int set_max_net_length  
net_length_value  
object_list
```

ARGUMENTS

net_length_value

Specifies the value to which the **max_net_length** attribute is to be set; that is, the maximum net length value.

object_list

Specifies a list of input ports and/or designs on which the **max_net_length** attribute is to be set.

DESCRIPTION

Sets the **max_net_length** attribute on the specified input ports and/or designs.

physopt attempts to ensure that the real net length in `on_route` mode or the net length estimation in `pre_route` mode for the nets driven by the specified ports or all nets in the specified design is less than the given value. There is no maximum value placed by default.

In cases where both a global `net_length` limit is set on a design, and a local value is set on a port, **physopt** attempts to meet the smaller (more restrictive) value.

In general, design rule constraints reflect technology-specific constraints that *must* be met for a design to function correctly. Optimization constraints are design goals and restrictions that are desirable but not crucial for the operation of a design. **physopt** attempts to meet all constraints placed on a design, but it gives priority to design rule constraints in the optimization process.

The **max_net_length** attribute specifies Maximum Net Length, a *design rule constraint*. Thus, **physopt** gives precedence to fixing a **max_net_length** violation, even if it adversely affects *optimization constraints* (for example, Maximum Delay and Maximum Area).

Use **report_constraint** to get information about optimization and design rule constraints.

To remove a maximum net length from a port or design, use **remove_attribute**. **reset_design** removes all attributes, including **max_net_length**, from the current design.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets a maximum net length of 100.0 micron on the design "mydesign":

```
prompt> set_max_net_length 100.0 mydesign
```

SEE ALSO

`report_constraint(2)`
`reset_design(2)`

set_max_time_borrow

Sets the **max_time_borrow** attribute to a specified value on clocks, latch cells, data pins, or clock (enable) pins, to constrain the amount of time borrowing possible for level-sensitive latches.

SYNTAX

```
int set_max_time_borrow  
delay_value  
object_list
```

ARGUMENTS

delay_value

Specifies the value to which the **max_time_borrow** attribute is to be set; defines the desired limit of time borrowing on the latches specified in **object_list**. *delay_value* must be between zero and the default maximum derived from the waveform. By default, the maximum is derived from the ideal clock waveform driving each latch, and is equal to (closing_edge - open_edge). Library setup and data-to-Q propagation times are automatically taken into account. *delay_value* is assumed to be in the same units as those in the technology library used during optimization.

object_list

Specifies a list of objects in the current design for which time borrowing is to be limited to *delay_value*. The objects can be clocks, latch cells, data pins, or clock (enable) pins. If a cell is specified, all enable pins on that cell are affected. Note that if the **max_time_borrow** attribute is set on a cell and the cell is replaced during optimization, the attribute is moved from the cell to the enable pin.

DESCRIPTION

Sets the **max_time_borrow** attribute to **delay_value** to constrain the amount of time borrowing possible for level-sensitive latches. To meet delay targets, **set_max_time_borrow** prevents automatic use of all or part of the enabling clock pulse on a latch.

To get **max_time_borrow** attributes on the design, use **get_attribute**.

To undo **set_max_time_borrow**, use **remove_attribute**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example restricts time borrowing on latches **latch1a** and **latch2f** to 4.0 units.

```
set_max_time_borrow  
2444
```

```
prompt> set_max_time_borrow 4.0 {latch1a latch2f}
```

The following example specifies that no time borrowing will take place on **latch1c**.

```
prompt> set_max_time_borrow 0.0 {latch1c}
```

SEE ALSO

`current_design(2)`
`remove_attribute(2)`

set_max_total_power

Sets the target total power for the current design by setting the **max_total_power** attribute to a specified value.

The **set_max_total_power** constraint will be obsolete in a future release. Use **set_max_leakage_power** and **set_max_dynamic_power** constraints as a replacement.

SYNTAX

```
int set_max_total_power  
total_power  
[GW | MW | KW | W | mW | uW | nW | pW | fW | aW]
```

Data Types

total_power float

ARGUMENTS

total_power

Specifies the maximum target total power of the current design; that is, the value to which the **max_total_power** attribute is to be set.

GW | MW | KW | W | mW | uW | nW | pW | fW | aW

Specifies the power dimension. If not specified, then the units of *total_power* are assumed to be the same as the units of *dynamic_power* in the technology library used during optimization.

DESCRIPTION

The **set_max_total_power** constraint will be obsolete in a future release. Use **set_max_leakage_power** and **set_max_dynamic_power** constraints as a replacement.

Sets the target (desired) total power for the current design by setting the **max_total_power** attribute. **max_total_power** is set to a value no greater than *total_power*. If **max_total_power** is set more than once for a design, the last value is used. The total power cost is the sum of leakage and dynamic power costs.

Note that if the leakage power units in the library differ from those for dynamic power, then the design leakage power is scaled to the dynamic power units.

To remove the **max_total_power** design attribute, use **remove_attribute** or **reset_design**.

To get information about the dynamic and leakage power usage of the current design, use **report_power**. To list the total power cost and constraint of the design, use **report_constraint**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets the target total power to zero for the current design. Since the constraint **0.0** can not realistically be met, `total_power` will be minimized.

```
prompt> set_max_total_power 0.0 mW
```

SEE ALSO

```
current_design(2)

report_constraint(2)
report_power(2)
reset_design(2)
set_max_dynamic_power(2)
set_max_leakage_power(2)
```

set_max_transition

Sets the **max_transition** attribute to a specified value on specified clocks group, ports or designs.

SYNTAX

```
int set_max_transition  
transition_value  
object_list
```

ARGUMENTS

transition_value
Specifies a maximum transition time for the specified clock groups, ports or designs. Sets the **max_transition** attribute to *transition_value* on the clock groups, ports or designs. *transition_value* must be expressed in units consistent with those in the technology library used during optimization. For example, if the library specifies drive values in kilohms and load values in picofarads, then *transition_value* must be expressed in nanoseconds.

object_list
Specifies a list of names of the clock groups, ports or designs for whose associated nets *transition_value* is set.

DESCRIPTION

Sets the **max_transition** attribute on the specified clock groups, ports or designs. **compile** attempts to ensure that the transition time for a net is less than the specified value. The maximum transition time for a net is defined as the least of the maximum transition times of the cell pins and design ports on that net.

In cases where both a global maximum transition time is set on a design and a local value is set on a port or clock group, **compile** attempts to meet the smaller (more restrictive) value.

If **max_transition** attributes are already specified in a technology library (implicit constraints), **compile** automatically attempts to meet them.

By default, no restriction is placed on the transition time for an input or output port, so the maximum transition time for the driven net is determined by the maximum transition times (if any) of the driven cell inputs or the driving cell output. By assigning a lower maximum transition time to a port, the maximum transition time for the net is reduced; thus, the design constraints are made more restrictive.

The **max_transition** constraint is a design rule constraint; thus, **compile** gives precedence to this constraint, even if it adversely affects optimization constraints on a design. **max_delay** and **max_area** are optimization constraints, whereas **max_fanout** and **max_transition** are design rule constraints. Design rule constraints reflect those technology-specific restrictions that must be met for a design to function correctly. Optimization constraints reflect goals and restrictions that are desirable, but not crucial for the operation of a design. Design Compiler attempts

to meet all constraints placed on a design, but gives priority to design rule constraints in the optimization process.

Use **report_constraint** to get information about optimization and design rule constraints.

Use **remove_attribute** to remove a maximum transition time from a port or design.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets a maximum transition time of 2.0 units on the port named "late_riser".

```
prompt> set_max_transition 2.0 late_riser
```

The following example specifies a maximum transition time of 2.0 units for the design "TEST".

```
prompt> set_max_transition 2.0 TEST
```

set_mcmm_job_options

Sets various job control options for Distributed MCMM.

SYNTAX

```
status set_mcmm_job_options
[-work_dir working_directory_path]
[-exec ICC_executable_path]
[-setup_script setup_script_name]
[-analysis_script analysis_script_name]
```

Data Types

<i>working_directory_path</i>	string
<i>ICC_executable_path</i>	string
<i>setup_script_name</i>	string
<i>analysis_script_name</i>	string

ARGUMENTS

-work_dir *working_directory_path*
Specifies the working directory where the Distributed MCMM jobs will be run.

-exec *ICC_executable_path*
Specifies the full path name of the ICC executable.

-setup_script *setup_script_name*
Specifies a TCL script that will be sourced by slave jobs.

-analysis_script *analysis_script_name*
Specifies a TCL script that will be sourced by slave jobs.

DESCRIPTION

This command allows you to set various options and parameters for running Distributed MCMM slave jobs. The most common parameters are set with the **set_host_options** command; **set_mcmm_job_options** is needed only for setting certain specialized parameters that are unique to distributed get_dominant_scenarios.

The *-work_dir* option specifies the full path to the working directory where all job files will be put, and where the jobs will actually be run. This directory should be accessible to all hosts that will run jobs. If it does not exist, the directory will be created. Otherwise, any existing files in it may be overwritten. If the *-work_dir* option is not given, Distributed MCMM will create a new directory under the current directory with a name of the form "mcmm_abc123".

The *-exec* option specifies an alternate ICC executable to be used by slave jobs. If this option is not given, the standard installed *icc_shell* will be used.

The *-setup_script* option specifies an optional user-written setup script to be sourced by each slave job. This script will be sourced once, at the beginning of the

slave job execution.

The *-analysis_script* option specifies an optional user-written analysis script to be sourced by each slave job. This script will be sourced immediately after each scenario is analyzed by the slave job. This can be useful for generating per-scenario reports.

The *-num_processes* option of the **set_host_options** command is used to specify how many slave jobs will be run. If a LSF or GRD compute pool is being used, the number of jobs will by default be the number of scenarios to be analyzed. If a host list is being used, the number of jobs will by default be the lesser of the number of scenarios to be analyzed, or the number of hosts specified. If the given value is greater than the number of scenarios to be analyzed, there will actually be only one job for each scenario. If the value is less than the number of scenarios, some of the jobs will analyze more than one scenario.

The *-submit_cmd* option of the **set_host_options** command is normally used to specify the full path name of the LSF or GRD job submission program. Distributed MCMM will use a default path name of this option is not given. For LSF, the default path name is */lsf/bin/bsub*. For GRD, the default path name is */usr/bin/qsub*. Note that the default GRD path name is unlikely to be correct for your installation; you will almost certainly need to specify the correct path name.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to override the executable and work dir.

```
prompt> set_mcmm_job_options -exec /usr/local/bin/my_icc_shell \
      -work_dir /remote/blah103/usr/joe/mcmm/my_work_dir
1
```

SEE ALSO

`set_host_options(2)`
`get_dominant_scenarios(2)`

set_message_info

Set some information about diagnostic messages.

SYNTAX

```
string set_message_info
-id message_id [-limit max_limit
| -stop_on]
```

Data Types

<i>message_id</i>	string
<i>max_limit</i>	integer

ARGUMENTS

-id *message_id*

Information is to be set for the given *message_id*. The message must exist. Although different constraints allow different message types, no constraint allows severe or fatal messages.

-limit *max_limit*

Set the maximum number of occurrences for *message_id*. This is an integer greater than or equal to zero. If you set it to zero, that means the number of occurrences of the message is unlimited. Messages which occur after a limit is reached are automatically suppressed.

-stop_on

Force Tcl error if message is emitted.

DESCRIPTION

The **set_message_info** command sets constraints on diagnostic messages (typically error, warning, and informational messages).

Currently, you can set an upper limit for the number of occurrences of a message. You can set this to zero to indicate that there is no limit. You can retrieve the current limit for a message using the **get_message_infocommand**. **When the limit is exceeded, all future occurrences of the message are automatically suppressed. A count of total occurrences (including those suppressed) can be retrieved using get_message_info.**

EXAMPLES

The following example uses **set_message_info** to set a limit on the number of APP-027 messages to 100. When the 101st APP-027 message is about to be issued, you will be warned that the limit has been exceeded, and that all future occurrences will be suppressed.

```
prompt> do_command
```

```
set_message_info
```

```
2452
```

```
Warning: can't find node U27.1 (APP-027)
Warning: can't find node U27.2 (APP-027)
Warning: can't find node U27.3 (APP-027)
Warning: can't find node U27.100 (APP-027)
Note - message 'APP-027' limit (100) exceeded. Remainder will be suppressed.
1
prompt>
```

`print_message_info(2)`
`suppress_message(2)`

set_min_capacitance

Sets the **min_capacitance** attribute to a specified value on specified input ports in the current design.

SYNTAX

```
int set_min_capacitance  
capacitance_value  
object_list
```

Data Types

capacitance_value	float
object_list	list

ARGUMENTS

capacitance_value

Specifies a value to which the **min_capacitance** attribute is to be set. *capacitance_value* must be expressed in units consistent with the technology library used during optimization. For example, if the library specifies capacitance values in picofarads, then *capacitance_value* must also be expressed in picofarads.

object_list

Specifies a list of names of the input and/or bidirectional ports on which the **min_capacitance** attribute is to be set.

DESCRIPTION

Sets the **min_capacitance** attribute to *capacitance_value* on the specified input ports. **compile** attempts to ensure that the load driven by the input port is not reduced below *capacitance_value*. The minimum capacitance value for a net is defined as the greatest of the minimum capacitance values of the driving cell pins and ports on a net.

If **min_capacitance** attributes are already specified in a technology library (implicit constraints), **compile** automatically tries to meet them.

By default, a port has no **min_capacitance** constraint.

min_capacitance, along with **max_fanout** and **max_transition**, is a *design rule constraint*; **max_delay** and **max_area** are optimization constraints. Design rule constraints reflect those technology-specific restrictions that must be met for a design to function correctly, while optimization constraints reflect goals and restrictions that are desirable, but not crucial for the operation of a design. Design Compiler attempts to meet all constraints placed on a design, but gives priority to design rule constraints in the optimization process. Therefore, **compile** gives preference to **min_capacitance** and other design rule constraints, even if they adversely affect optimization constraints on a design.

To get information about optimization and design rule constraints, use **report_constraint**; to get information on the current port settings, use **report_port**. To remove the **min_capacitance** attribute from a port, use **remove_attribute**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets a minimum capacitance value of 12.0 units on the port named "high_drive":

```
prompt> set_min_capacitance 12.0 high_drive
```

SEE ALSO

`all_inputs(2)`

`report_port(2)`
`reset_design(2)`
`set_max_capacitance(2)`

set_min_delay

Specifies a minimum delay target for paths in the current design.

SYNTAX

```
int set_min_delay
delay_value
[-rise | -fall]
[-from from_list
 | -rise_from rise_from_list
 | -fall_from fall_from_list]
[-through through_list]
[-rise_through rise_through_list]
[-fall_through fall_through_list]
[-to to_list
 | -rise_to rise_to_list
 | -fall_to fall_to_list]
[-reset_path]
```

Data Types

delay_value	float
from_list	list
rise_from_list	list
fall_from_list	list
through_list	list
rise_through_list	list
fall_through_list	list
to_list	list
rise_to_list	list
fall_to_list	list

ARGUMENTS

delay_value
Specifies the value of the desired minimum delay for paths between startpoints and endpoints. Express *delay_value* in the same units as the technology library used during optimization. If a path startpoint is on a sequential device, clock skew is included in the computed delay. If a path startpoint has an input external delay specified, that delay value is added to the path delay. If a path endpoint is on a sequential device, clock skew and library setup time are included in the computed delay. If the endpoint has an output external delay specified, that delay is added into the path delay.

-rise | -fall
Specifies whether endpoint rising or falling delays are constrained. If neither is specified, both rising and falling delays are constrained.

-from from_list
Lists the path startpoints (port, pin, clock, or cell names) of the current design. If a clock is specified, all path startpoints related to that clock

are affected. If you specify a cell name, one path startpoint on that cell is affected. All paths from these startpoints to the endpoints in the *to_list* are constrained to *delay_value*. If you do not specify *to_list*, all paths from *from_list* are affected. This list cannot include output ports. If more than one object is included, enclose the objects in double quotation marks ("") or in braces ({}).

-rise_from *rise_from_list*

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Same as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through *through_list*

Lists the path throughpoints (port, pin, or leaf cell names) of the current design. The minimum delay value applies only to paths that pass through one of the points in the *through_list*. If you include more than one object, enclose the objects in double quotation marks ("") or in braces ({}). If you specify the **-through** option multiple times, the minimum delay values apply to paths that pass through a member of each *through_list* in the order the lists were given. The path must first pass through a member of the first *through_list*, then through a member of the second list, and so on for every through list specified. If you use the **-through** option in combination with the **-from** or **-to** options, the minimum delay applies only if the **-from** or **-to** conditions are satisfied and the **-through** conditions are satisfied.

-rise_through *rise_through_list*

Same as the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than once in a single command invocation as with the **-through** option.

-fall_through *fall_through_list*

Same as the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than once in a single command invocation as with the **-through** option.

-to *to_list*

Lists the path endpoints (port, clock, cell, or pin names) of the current design. All paths to the endpoints in the *to_list* are constrained to *delay_value*. If you do not specify *from_list*, all paths to *to_list* are affected. This list cannot include input ports. If more than one object is included, enclose the objects in either double quotation marks ("") or in braces ({}). If you specify a cell, one path endpoint on that cell is affected. If you specify a clock, all path endpoints related to that clock are affected.

```

-rise_to rise_to_list
    Same as the -to option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of -to, -rise_to, and -fall_to.
-fall_to fall_to_list
    Same as the -to option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of -to, -rise_to, and -fall_to.
-reset_path
    Removes existing point-to-point exception information on the specified paths. Only information of the same rise and fall setup or hold type is reset. This is equivalent to using the reset_path command with similar arguments before the set_min_delay command is issued.

```

DESCRIPTION

This command sets the minimum delay target for paths in the current design. Minimum delay is considered as an optimization constraint by the **compile** command. If a path violates the requirement given in a **set_min_delay** command, **compile** adds delay to fix the violation if maximum delay cost is not increased. You can prioritize minimum delay cost using the **set_cost_priority** command.

The value of a **min_rise_delay** attribute can never be greater than that of a **max_rise_delay** attribute for the same path (and similarly for fall attributes). If this occurs, the old attribute is removed.

Individual minimum delay targets are automatically derived from clock waveforms and port input or output delays. For more information, refer to the **create_clock**, **set_input_delay**, and **set_output_delay** command man pages.

The **set_min_delay** command is a point-to-point timing exception command. It overrides the default single-cycle timing relationship for one or more timing paths. Other point-to-point timing exception commands include **set_multicycle_path**, **set_max_delay**, and **set_false_path**.

If a path satisfies multiple timing exceptions, the following rules determine which exceptions take effect. Rules referring to **-from** apply equally to **-rise_from** and **-fall_from**, and similarly for the rise and fall options of **-through** and **-to**.

1. Two **group_path** commands can conflict with each other, but a **group_path** exception alone does not conflict with another type of exception. Therefore, the remaining rules apply for two **group_path** exceptions, or two non **group_path** exceptions.
2. If both exceptions are **set_false_path**, there is no conflict.
3. If one exception is a **set_max_delay** and the other is a **set_min_delay**, there is no conflict.
4. If one exception is a **set_multicycle_path -hold** and the other is a **set_multicycle_path -setup**, there is no conflict.
5. If one exception is a **set_false_path** and the other is not, the **set_false_path**

takes precedence.

6. If one exception is a **set_max_delay** and the other is not, the **set_max_delay** takes precedence.
7. If one exception is a **set_min_delay** and the other is not, the **set_min_delay** takes precedence.
8. If one exception has a **-from pin** or **-from cell** and the other does not, the one with the **-from pin** takes precedence.
9. If one exception has a **-to pin** or **-to cell** and the other does not, the one with the **-to pin** takes precedence.
10. If one exception has any **-through** points and the other does not, the one with **-through** points takes precedence.
11. If one exception has a **-from clock** and the other does not, the one with the **from clock** takes precedence.
12. If one exception has a **-to clock** and the other does not, the one with the **-to clock** takes precedence.
13. The exception with the more restrictive constraint then takes precedence. For **set_max_delay** and **set_multicycle_path -setup**, this is the constraint with the lower value. For **set_min_delay** and **set_multicycle_path -hold**, it is the constraint with the higher value.

To remove information set by **set_min_delay**, use the **reset_path** or **reset_design** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

In the following example, the **set_min_delay** command requires that any delay path that passes through the U1 cell and ends at the Y port is greater than 12.5 time units:

```
prompt> set_min_delay 12.5 -through U1 -to Y
```

The following example specifies that all paths from A1 and A2 to Z5 must be greater than 4.0 units:

```
prompt> set_min_delay 4.0 -from {A1 A2} -to Z5
```

The following example command sets a minimum delay requirement of 3.0 for all paths that first pass through either u1/Z or u2/Z and then pass through u5/Z or u6/Z:

```
prompt> set_min_delay 3.0 -through {u1/Z u2/Z} -through {u5/Z u6/Z}
```

The following example specifies that all timing paths from ff1/CP to ff2/D that rise through one or more of {U1/Z U2/Z} and fall through one or more of {U3/Z U4/C} must have delays greater than 3.0 units.

```
prompt> set_min_delay 3.0 -from ff1/CP -rise_through {U1/Z U2/Z} -fall_through {U3/Z U4/C} -to ff2/D
```

reset_path(2)
set_cost_priority(2)
set_fix_hold(2)
set_max_delay(2)

set_min_library

Sets an alternate library to use for minimum delay analysis.

SYNTAX

```
int set_min_library  
max_library  
-min_version min_library | -none
```

Data Types

<i>max_library</i>	string
<i>min_library</i>	string

ARGUMENTS

max_library
Specifies the library file name to use as a link_library or target_library. This library is used for maximum delay analysis only. Do not include the path to the library file name.

-min_version min_library
Specifies the library file name that corresponds to the *max_library* and uses it for minimum delay analysis. The *min_library* should not be specified in the link_library or target_library. Do not include the path to the library file name.

-none
Unsets the setting of a minimum library.

DESCRIPTION

The **set_min_library** command creates a minimum/maximum relationship between two library files. The *max_library* is used for maximum delay analysis and the *min_library* is used for minimum delay analysis.

Whenever the tool computes a minimum delay value, it first consults the library cell from the max library. If a library cell exists with the same name, the same pins, and the same timing arcs in the min library, the timing information from the min library is used. If the tool cannot find a matching cell in the min library, the max library cell is used.

Do not include the path to the *max_library* nor *min_library* file name. Specify the path to those library files in \$search_path.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example is a typical usage of **set_min_library**:

```
prompt> set link_library "LIB_WC_COM.db"
prompt> set target_library $link_library
prompt> set_min_library LIB_WC_COM.db -min_version LIB_BC_COM.db
prompt> set_operating_conditions -max WC_COM -max_library LIB_WC_COM \
    -min BC_COM -min_library LIB_BC_COM
prompt> report_timing -delay max
prompt> report_timing -delay min
```

SEE ALSO

`link(2)`
`set_operating_conditions(2)`
`link_library(3)`
`target_library(3)`

set_mode

Selects the mode of a component.

SYNTAX

```
int set_mode
[mode_list]
[instance_list]
```

Data Types

<i>mode_list</i>	list
<i>instance_list</i>	list

ARGUMENTS

mode_list
Specifies the active modes for timing analysis. All other modes of the given mode group are implicitly inactive. The specified modes are active on the given instance list.

instance_list
Specifies the cells for which the specified modes are active.

DESCRIPTION

The **set_mode** command is used to select the active mode of a cell that has several functional modes. The other modes in the mode group that are not selected are disabled.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command selects the READ mode for the RAM instance Uram1.

```
prompt> set_mode READ Uram1
```

SEE ALSO

```
report_mode(2)
reset_mode(2)
```

set_mpc_macro_array

Specifies an array of macro cells.

SYNTAX

```
int set_mpc_macro_array
-name string
-elements list
[-align_edge t | b | l | r | c | top | bottom | left | right | center]
[-align_pins {ref_pin const_pin}]
[-x_offset float]
[-y_offset float]
[-use_keepout_margin]
[-vertical]
[-rectilinear]
[-align_2d lb | lc | lt | rb | rc | rt | cb | cc | cr | left-bottom | left-center | left-top | right-bottom | right-center | right-top | center-bottom | center-center | center-top]
[-verbose]
[-reset]
```

ARGUMENTS

-name *string*

Specifies name for the macro array. This is a mandatory option.

-elements *list*

This option specifies list-of-list of macro cells which will compose the array. Each sub list represents a row in the array. An array starts from top most row. A row starts from left. For example, to specify an array like following

A11 A12 A13

A21 A22 A23

A31 A32 A33

```
-elements [list [list A11 A12 A13] \
           [list A21 A22 A23] \
           [list A31 A32 A33]]
```

You can use the **get_cell** command to obtain the macro cell object. For example, [**get_cell RAM1**]. Note that [get_cell xx] won't work between double-quotes or curly braces. For example, you can't get a list of collection using "[get_cell A] [get_cell B]", instead you should use [list [get_cell A] [get_cell B]]. This argument is mandatory.

-align_edge *t | b | l | r | c | top | bottom | left | right | center*

Specifies an edge for the macro cells in one row to align with. This option is not mandatory. Default is to align to the centers.

-align_pins {*ref_pin const_pin*}

Align with pins. 'ref_pin' is the name of a pin on reference cell (first cell in the array). 'the_pin' is the name of a pin from second cell. This option takes effect only if specified array has two macro cells.

-x_offset float
 Specifies the distance between two adjacent edges of macro cells on one ROW. Unit is micron. Default value is 0, which means the cells will abut to each other.

-y_offset float
 Specifies the distance between two adjacent edges of macro cells on the same column of the next row. Unit is micron. Default value is 0, which means the cells will abut to each other.

-use_keepout_margin
 Specifies the tool to use keepout margin to determine the spacing between two adjacent rows and/or columns of the array. This option is mutually exclusive with -x_offset and -y_offset options.

-vertical
 If specified for one dimensional array, it causes the command to arrange one dimensional macros in a vertical column. By default these arrays are created as horizontal rows (unless you specify each cell in a separate list in the list). If specified for two dimensional array, it causes the command to arrange the array in column based structure, instead of row based structure. It is like rotate a two dimensional array 90 degrees.

-rectilinear
 This option is for design planning only. This option is for 2D array. It specifies that the overall shape of the 2D array is rectilinear. For a rectilinear macro array, you can specify different number of cells in different rows. This option is not mandatory. By default, in design planning, a 2D macro array is placed as a single object that is rectangular in shape, and all the rows in the array have the same number of cells.

-align_2d lb | lc | lt | rb | rc | rt | cb | cc | cr | left-bottom | left-center | left-top | right-bottom | right-center | right-top | center-bottom | center-center | center-top
 "left-bottom | left-center | left-top | right-bottom | right-center | right-top | center-bottom | center-center | center-top" This option is for design planning only. This option is for heterogeneous 2D array. It specifies edges for the macro cells in a row or column to align with in a heterogeneous 2D macro array. This option is not mandatory. Default is to align the cells in the same column by their left edge, and align the cells in the same row by their bottom edge.

-verbose
 Lets the tool print out information about what you have specified for each row and what object the tool is getting. This switch can be used to make sure the -elements option does create an array as you expected.

-reset
 Removes the relative constraints between these macro cells and removes the macro array as an object.

DESCRIPTION

The **set_mpc_macro_array** command Defines an array of macro cells. The tool sets

relative location constraints between macro cells in the array according to the parameters specified for the array.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to specify a 2x2 array for cell A11 A12 A21 A22 with 10 microns space between rows and columns.

```
prompt>set_mpc_macro_array
      -name AA
      -elements [list [list A11 A12]
                  [list A21 A22]]
      -x_offset 10
      -y_offset 10
```

SEE ALSO

```
create_placement(2)
report_mpc_macro_options(2)
report_mpc_macro_array(2)
set_mpc_options(2)
set_mpc_port_options(2)
```

set_mpc_macro_options

Specifies constraints on the specific floorplan macro cells and macro arrays in MPC flows.

SYNTAX

```
int set_mpc_macro_options
[list_of_macro_objects]
-legal_orientations list
-anchor_bound {tl | t | tr | r | br | b | bl | l | tm | bm | lm | rm | c}
-x_offset float
-y_offset float
-align_pins list
-snap_to_edge side_and_float_list
-edge_channel float
-side_channel {left_right_top_bottom}
-group_name string
-group_spacing float
-reset
```

ARGUMENTS

list_of_macro_objects

This option specifies a list of macro cells the command applies to. Use the **get_cell** command to obtain the macro cell object. For example, [**get_cell Input***]. You can also specify macro array names to constraint them using the above switches. This argument is mandatory.

-legal_orientations list

Specify the legal orientation of the macro cells so that the placement tool will optimize the macro cell orientation within the defined values of the -legal_orientations option. The value can be one or more than one of the 8 possible orientations represented by following strings.

PDEF syntax: 0, 90, 180, 270, 0-mirror, 90-mirror, 180-mirror, 270-mirror

DEF syntax: N, W, S, E, FN, FW, FS, FE

This option will overwrite the legal orientations defined in library. If user does not specify this option, then the macro cell's library legal orientation will be used in the placement.

User can specify a single legal orientation to force the placer to place the cell in the fixed orientation.

User cannot specify orientation for macro arrays.

-anchor_bound {tl | t | tr | r | br | b | bl | l | tm | bm | lm | rm | c}

Specifies a macro cell's anchor bound (a kind of placement move bound).

The valid keywords and their definitions are shown below:

Keyword	Definition
---------	------------

-----	-----
-------	-------

tl	top-left corner
----	-----------------

t	top
---	-----

tr	top-right corner
----	------------------

r	right
br	bottom-right corner
b	bottom
bl	bottom-left corner
l	left
tm	top-middle
bm	bottom-middle
lm	left-middle
rm	right-middle
c	center

This anchor bound constrains the placement tool so that it places the macro cell in one of the boundary areas of the block. This forces the macro cell to stay at one of the boundaries of the block. The default move bound will be one-half or one-quarter of the core area associated with the specified anchor boundary. For example, if you specify -anchor_bound as **t**, the move bound will be the top half of the core area. If you specify -anchor_bound as **tr**, the move bound will be the top-right area of the core area. If the one-half or one-quarter core area is not large enough to hold the macro cell, with any set of dimensions, the move bound is set to cell width or height in that dimension.

The type of the -anchor_bound is SOFT, which means that placement can always move the macro cell out of the bound in case there is no space and the cost is too high.

You can specify -anchor_bound for macro arrays.

-x_offset float

-y_offset float

Specifies the distance between the constrained element and the core edges. If the -anchor_bound is t, b tm or bm, user should specify only -y_offset. If the -anchor_bound is l, r, lm or rm, user should specify only -x_offset. If the -anchor_bound is tl, tr, bl or br, user can specify -x_offset or -y_offset or both.

-align_pins list

Aligns a specific port to a pin of constrained macro cell. The argument passed with this switch is a list of two pins; reference pin followed by constrained pin. For example, `set_mpc_macro_options [get_cell A1] -anchor_bound t -align_pins [list DATA[0] [get_pins A1/DATA[0]]]`.

-snap_to_edge side_and_float_list

Specify this when you want to place the macro exactly an offset away from each side specified. Offset defaults to 0 if not provided. You can provide a list of side and offset values as input. The side could be either full name or single letter abbreviation. (Left, LEFT, L)

-edge_channel float

Specify this when you want to place the macro atleast some distance between the core and the macro. MPC will place the macro the channel distance away from each side.

-side_channel {left_right_top_bottom}

Specify this when you want to place the macro at least some distances away from the core edge and the distance on each side are different.

```

-group_name string
    Provide a name for the group of macros which you try to specify
    'group_spacing'. Without specifying it, the tool will generate a default name
    for the group.

-group_spacing float
    Specify this when you want to place the macros in the input list atleast some
    distance away from each other . This will create a group with a default name
    if none provided.

-reset
    Removes the attributes set with previous uses of the set_mpc_macro_options
    command.

```

DESCRIPTION

The **set_mpc_macro_options** command sets the constraints for the macro cell and macro array in the minimal physical constraints flow. The command constrains the **create_placement -mpc**, **physopt -mpc**, and **compile_physical -mpc** commands in placing the macro cells in the floorplan. You use this command before **create_placement -mpc** or **compile_physical -mpc** in the Tcl source file. Use this command after you load the physical library and the design.

This command is also available using the GUI, which provides a dialogue box for easy interface to create macro option constraints.

You can use this command to restrict macro cells and macro arrays in different ways:

- To a particular region, by specifying the **-anchor_bound** option.
- During the macro cell placement, by constraining with the **-legal_orientation** option, and the library legal orientations. Macro cell orientation must be one of the legal orientations.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to place the cell RAM1 only on the top-right corner of the core area and in south orientation.

```

prompt>set_mpc_macro_options [get_cell "RAM1"] \
    -legal_orientation S -anchor_bound tr
prompt>set_mpc_macro_options ICRamMacroArray \
    -anchor_bound tr
prompt>set_mpc_macro_options [all_macro_cells] -group_space 30
prompt>set_mpc_macro_options \
    -snap_to_edge "left 10 right 20" ICRamMacroArray

```

```
prompt>set_mpc_macro_options \
    -snap_to_edge "l right 20" ICRamMacroArray
prompt>set_mpc_macro_options \
    -snap_to_edge "l 2 r t b 20" ICRamMacroArray
prompt>set_mpc_macro_options \
    -edge_channel 30 ICRamMacroArray
prompt>set_mpc_macro_options \
    -side_channel {20 30 30 0} ICRamMacroArray
prompt>set_mpc_macro_options \
    -group_spacing 30 [all_macro_cells]
```

set_mpc_options

Specifies the constraints used to generate the floorplan in the create_placement -mpc flow, the compile_physical -mpc flow, or the physopt -mpc flow.

SYNTAX

```
int set_mpc_options
-utilization util
-aspect_ratio y_x_ratio
-row_direction {h | v}
-origin {X Y}
-top_port_limit limit_value
-bottom_port_limit limit_value
-left_port_limit limit_value
-right_port_limit limit_value
-horz_port_layer_name layer
-vert_port_layer_name layer
-min_port_pitch integer
-routing_track_offset_x {h | f}
-routing_track_offset_y {h | f}
-io_margin_left margin_value
-io_margin_right margin_value
-io_margin_top margin_value
-io_margin_bottom margin_value
-corner_keepout distance
-core_width width
-core_height height
-first_row_orientation orient
-dont_snap_port
-dont_promote_layer
-shift_to_center
-rectilinear_outline
-reset
```

Data Types

<i>util</i>	float < 2.0
<i>y_x_ratio</i>	float
<i>X</i>	float
<i>Y</i>	float
<i>limit_value</i>	integer
<i>layer</i>	string
<i>integer</i>	<i>limit_value</i>
<i>margin_value</i>	float
<i>distance</i>	float
<i>width</i>	float
<i>height</i>	float
<i>orient</i>	string

ARGUMENTS

-utilization *util*

Specifies target placement utilization for core area. The utilization is defined as standard cell utilization:

total_standard_cell_area / (core area - blockage area - macro_cell_area)

Area Definition

Core area Core area bounding box

Standard cell area sum of fixed and non-fixed standard cell area

blockage area sum of placement keepout area and filler cell (physical only cell) area

macro_cell area sum of fixed and non-fixed macro cell area
Note: for utilization calculation purpose, we define the macro cell as the cell in the netlist without lib site linked, or the cell width and height is larger than 5 minimum lib site height.

Value for this option is a float number less than 2. For example, 0.85 for 85% utilization. This option also related to following options: -core_width, -core_height and -aspect_ratio. See DESCRIPTION below for some details. The default value is 0.60.

-aspect_ratio *y_x_ratio*

Specifies aspect ratio for core area which is y:x ratio. For example, specifying 2 for this option will result a core area whose y dimension is 2 times of x dimension. This option also related to following options: -core_width, -core_height and -utilization. See DESCRIPTION below for details. The default value is 1.0.

-row_direction {*h* | *v*}

Specifies direction for core site array. The value can be one of horizontal (*h*) or vertical (*v*). The default direction is horizontal.

-origin {*X Y*}

Specifies the coordinates of lower-left corner of core area. The unit is micro in float format. The default value is {0.0 0.0}.

-top_port_limit *limit_value*

-bottom_port_limit *limit_value*

-right_port_limit *limit_value*

-left_port_limit *limit_value*

Specifies the limit of the number of pins on the each side of core area. Require an integer value for this constraint. The tool will not place more than than the specified number of pins on each side. These limits have no effect if the -dont_snap_port option is set. It is integer type. The default value is none, e.g. unlimited.

-horz_port_layer_name layer
-vert_port_layer_name layer
 Specifies the order of port layer names on each direction which the program uses to place ports. If user does not specify the port layer in set_mpc_port_options command, the program will use these layer names as the port layer where the ports will be placed.
 The horizontal port layers apply to the ports located on left and right side of the block. The vertical port layers apply to the ports located on top and bottom side of the block.
 If not specified, the tool will look at layers defined in physical library and picks the second encountered routing layer on the prefered direction as default layers for ports. This options takes comma or space seperated metal names as input.

-min_port_pitch integer
 Specifies the minimum metal pitch distance between two ports. Default is 1, which means ports can be placed at adjacent tracks.

-routing_track_offset_x {h | f}
 Specifies x offset to origin of core area for vertical routing tracks. The value can be one of h (half metal pitch) or f (full metal pitch). The default offset is half metal pitch.
 Note that the offset is relative to the origin of core area. Routing tracks will cover die area if different from core area.

-routing_track_offset_y {h | f}
 Specifies y offset to origin of core area for horizontal routing tracks. The value can be one of h (half metal pitch) or f (full metal pitch). The default offset is half metal pitch.
 Note that the offset is relative to the origin of core area. Routing tracks will cover die area if different from core area.

-io_margin_top margin_value
-io_margin_bottom margin_value
-io_margin_left margin_value
-io_margin_right margin_value
 Specifies the I/O margin on each side. These distances are used to calculate DIEAREA defined in PDEF. It is float type. The unit is micron. The default value is 0.

-corner_keepout distance
 Specifies a distance to keep ports away from corners. If the specified value is less than 1, it is used as a percentage to the length of core edges. Otherwise, it is an absolute distance from the corner, unit is micron. Default value is 0.

-core_width width
-core_height height
 Specifies width and height of the core area. These options are also related to following options: -utilization and -aspect_ratio. See DESCRIPTION below

for details. It is float type. Unit is micron. No default value for the options.

-first_row_orientation orient
 Specifies the orientation of the sites on the bottom row (first row) of the placement area. In the placement area, the rows are placed in flip pattern, e.g. if the first row of sites are orient in 0 (N), the second row of sites will be orient in 180-Mirror (FS). You should check the physical library (LEF or .plib) to check the legal site orientations. An error is generated if you specify an illegal orientation. Default is 0 or NORTH.
 PDEF syntax: 0, 90, 180, 270, 0-mirror, 90-mirror, 180-mirror, 270-mirror DEF syntax: N, W, S, E, FN, FW, FS, FE

-dont_snap_port
 By default, the command snaps ports to block boundaries automatically. This option can switch off the port snapping if you want to see the ports at the locations from placement.

-dont_promote_layer
 By default, the command tries to place the ports on all available track on all layers. The command tries to exhaust all the tracks on all the layers. If you strictly want the tool to use just the layers specified by using -vert_port_layer_name and -horz_port_layer_name, use this option.

-shift_to_center
 By default, the origin (0 0) of core area is at lower-left corner. This option tells the tool to generate core area with origin (0 0) at the center.

-rectilinear_outline
 This indicates to the mpc flow to treat the keepouts defined on the core boundary to be treated as rectilinear boundary for the core. This will be another way to specify the rectilinear outline. Also see set_mpc_rectilinear_outline command.

-reset
 Removes all the attributes set by previous set_mpc_options commands. If there is default value, it will be set back to default value.

DESCRIPTION

This command defines design level physical constraints, so called MPC constraints. create_placement -mpc, compile_physical -mpc and physopt -mpc commands will take these constraints in generating coarse floorplan. User should use this command before the create_placement -mpc, physopt -mpc or compile_physical -mpc command in tcl source file. Also, user should use this command after the physical library and the design are loaded.

Following options are related and may causes conflicts. User should prevent the conflict when using them. Program will error out if there is any conflict which cannot be resolved. -utilization -aspect_ratio -core_width -core_height

There is no conflict when using -utilization together with -aspect_ratio; However, there may be conflict when using -core_width and -core_height together. Following table shows all the possible conflicts may occur. User should not use these options

together. From the table we can conclude that any 3 of them cannot use together. Every 2 of them can be used together.

util	ratio	width	height	CONFLICT?

use	use	use	use	YES
no	use	use	use	YES
use	no	use	use	YES
use	use	no	use	YES
use	use	use	no	YES
no	no	no	use	YES
no	no	use	no	YES
all other usages produce no conflicts				

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to set floorplan options for current design. It sets the floorplan utilization to 85%, placement area aspect_ratio (y:x) to 2:1, horizontal row placement; and the first row has the site orientation of 0-mirror (e.g., FN, Flip-North), and the left-lower corner of the placement area is (10 10) micron. Also it sets that the placement tool can only place 10 ports on top side of the block.

```
prompt> set_mpc_options \ -utilization 0.85 \ -aspect_ratio 2.0 \ -row_orientation h \ -first_row_orientation 180-Mirror \ -origin {10.0 10.0} \ -top_port_limit 10
```

```
prompt> set_mpc_options \ -horz_port_layer_name "M5,M7,M3" \ -vert_port_layer_name "M4 M6 M2" \ -dont_promote_layer
```

```

set_mpc_pnet_options

Specifies the constraints for pnet generation in the floorplan in the create_placement -mpc or physopt -mpc flows.

SYNTAX

```
int set_mpc_pnet_options
-name pnet_name
-reset
-layer layer_name
-type pwr | gnd
-width float
-pitch float
-offset float
-direction {h | v}
-model_vias
-mult_via_x float
-mult_via_y float
```

Data Types

<i>pnet_name</i>	string
<i>layer_name</i>	string

ARGUMENTS

```
-name pnet_name
    Unique name for the pnet. Used to create the name of the pnet.

-reset
    Removes the attributes set by previous set_mpc_pnet_options commands.

-layer layer_name
    Name of the layer the pnet trunk is to be drawn. Defined in the plib library.

-type pwr | gnd
    Type of the pnet must be one of pwr (power) or gnd (ground).

-width float
    Width of the power trunk.

-pitch float
    Center to center distance between two trunks.

-offset float
    Distance from the left of die or core for vertical trunks and Distance from
    the bottom for horizontal trunks.

-direction {h | v}
    The direction must be one of h (horizontal) or v (vertical). If the direction
    is not specified, the tool uses the preferred direction for the layer, as
    defined in the library.
```

```

-model_vias
    Should model vias for the layers in between.

-mult_via_x float
    When modeling vias for pnets between trunk site or trunk to trunk pnets this
    value is to be used to generate a via model with width on x axis multiplied
    by this number.

-mult_via_y float
    When modeling vias for pnets between trunk site or trunk to trunk pnets this
    value is to be used to generate a via model with width on y axis multiplied
    by this number.

```

DESCRIPTION

This command specifies the pnet options, which are used to create power trunks and model via in the `create_placement -mpc` command. You should issue these commands after the design and physical libraries are loaded.

During the flow the options would be read and the trunks would be drawn based on the options provided.

The generated pnets could be viewed after generation using the command `report_pnet -only_physical`.

The generated pnets can be removed using the `remove_net -only_physical [get_pnet name]` command. Please see the example.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to specify options for trunk type metal6_pwr on layer metal6 using the widths and pitch. Followed by reporting and removing the generated pnet.

```

prompt> set_mpc_pnet_option -layer Metal6 \
    -name gnd_metal6 -width 3.00 -pitch 16.00 \
    -type gnd -offset 5.10 -direction v \
    -model_via -mult_via_x 3.3 -mult_via_y 6.6

prompt> report_net -only_physical

prompt> get_pnet

prompt> remove_net -only_physical [get_pnet gnd_metal6]

```

report_mpc_macro_options(2)

set_mpc_port_options

Specifies the constraints for ports in the floorplan in the create_placement -mpc, the physopt -mpc, or the compile_physical -mpc flows.

SYNTAX

```
int set_mpc_port_options
-side {l | r | t | b}
-x_bounds {min max}
-y_bounds {min max}
-layer layer_name
-group
-group_name group_name
-order {cw | ccw}
-pitch int
-start_location {x y}
-pin_order int
-offset float
-width float
-height float
-dont_snap
-reset
[port_list]
```

Data Types

<i>min</i>	float
<i>max</i>	float
<i>layer_name</i>	string
<i>group_name</i>	string
<i>x</i>	float
<i>y</i>	float
<i>float</i>	Y
<i>port_list</i>	list or collection

ARGUMENTS

```
-side {l | r | t | b}
      Specifies the side to which the ports should snap. The value is one of l
      (left), t (top), b (bottom), r (right). This option has no effect if -
      dont_snap_pins is used in the set_mpc_options command. By default there is
      no side constraint on the ports. The ports are snapped to the nearest side
      of the block.

-x_bounds {min max}

-y_bounds {min max}
      Specifies the bound for the ports. Floating point numbers from 0.0 to 1.0
      will be taken as percentage of the core x- or y-dimension. Values greater
      than 1.0 are of unit micron. The created bound is a hard bound. By default
      there are no bounds for the ports (the ports can be placed anywhere along the
      side of the placement area). Be careful when specifying the bound to avoid
```

conflicts with the -side specification. If conflicts occur the -side specification takes priority. For example, if you specify -side top, the -y_bound specification is ignored.

-layer *layer_name*

Specifies layer name of the port geometry.

If you do not specify the layer name, the program uses the default layer name as set by the **set_mpc_options** command.

-group

Indicates that the list of ports should be grouped together. No other ports should be introduced in between. You can use the -group_name option to specify a name for the port group. If you do not specify a name for the port group, the tool generates a default name for it. If you do not specify the -order option, the tool does not consider the port ordering.

-group_name *group_name*

Specifies a name for the port group. This argument is optional.

If you do not specify this option, the tool generates a default name.

-order {cw | ccw}

Specifies that the specified ports should be kept in clockwise or counterclockwise order. Valid values for this argument are cw (clockwise) or ccw (counterclockwise). If you do not specify -group, other ports might be placed in the space between ports.

-pitch *int*

Specifies the space between two ports in the group. The value of the integer is the number of pitches of the port layer. This argument is optional.

If you do not specify this option, the value specified by the -min_port_pitch option of the **set_mpc_options** command is used, or 1 pitch is used as the default.

-start_location {*x y*}

Specifies the location of the first port of the group. You can specify the start location using either absolute coordinates or relative coordinates (float numbers of $0 < x \leq 1$, $0 < y \leq 1$ are interpreted as a percentage of the x-dimension or y-dimension of the core area). This argument can only be used with -group. Use of this argument implies -order.

-pin_order *int*

Specifies the order for the pin (as per the TDF syntax). The order could be integer number from (0..32767) If a port has a pin_order value of 0, the placement of the pin to the other pins is not important. If a port has a pin_order value of 1, no pin can be placed between the pin and corner of the boundary. If a port has a pin_order value of 2, any number of pins can be placed between the pin and the corner of the boundary. If two pins have consecutive pin_order no pins can be placed between them. If a group of pins has the same pin_order value, no other pins can be placed between any two of the pins in the group. In this case, ordering inside the group is not important. However, the placement of the group relative to the other pins on the same side is determined by the pin_order value.

-offset *float*

Relative offset of the pin placement from the bottom edge or the left edge

of the cell boundary. Valid values: Any number (in distance unit) that is greater than the height of the tallest pin in the layout. A negative number to indicate that you do not want to place an offset constraint on the pin. In case of contradiction between constraints If you specify a offset value that contradicts the specified pin order, offset value will be relaxed. If you specify two offset values that contradict each other, the offset constraint with the lowest pin_order value will be considered.

-width float

Specifies the dimension along the cell boundary. Must be used along with the -height switch.

-height float

Specifies the dimension of the port from the boundary towards the center of the cell. Must be used along with the -width switch.

-dont_snap

Specifies that the port should not be snapped to the core or the io margin boundary. You can specify this for each individual port.

-reset

Removes the attributes set by previous set_mpc_port_options commands.

port_list

Specifies the list of ports that this command applies to. This argument is mandatory.

DESCRIPTION

This command specifies the port constraints for MPC. It constrains the create_placement -mpc and compile_physical -mpc commands in placing the ports in the floorplan. Use this command after loading the physical library and design, but before running the create_placement -mpc or compile_physical -mpc command.

The ports are snapped to the specified side. If you do not specify a side, the ports are snapped to the side nearest to the port location assigned by the coarse placer. If you specify -dont_snap_pins in the **set_mpc_options** command, the ports are not snapped to the sides of the block. If you specify constraint -dont_snap on a pin, that pin is not snapped to the side of the block.

if -height and -width constraints are provided shape for the pin will be created if not already present, after the cell is fixed.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to constrain placement of the o1 port to the top side of the block.

```
prompt> set_mpc_port_options [get_port "o1"] -side top prompt>
set_mpc_port_options [get_port "o1"] -dont_snap
```

set_mpc_rectilinear_outline

Specifies the rectilinear outline constraint for the core generation in create_placement -mpc, physopt -mpc or compile_physical -mpc flows.

SYNTAX

```
int set_mpc_rectilinear_outline
    -coordinates list_of_floats
    -reset
    -verbose
```

ARGUMENTS

```
-coordinates list_of_floats
    List of enclosing coordinates for the rectilinear outline shape.

-reset
    Removes the attributes set by previous set_mpc_rectilinear_outline commands.

-verbose
    Reports verbose messages.
```

DESCRIPTION

This is the command for specifying the rectilinear core outline in the create_placement -mpc, physopt -mpc and compile_physical -mpc flows. MPC will create a rectangular core from this outline. Places placement and wiring keepouts on the core to model a rectilinear core.

This rectilinear outline is used by MPC flow to create
Rectangular core area.

Placement and Wiring keepouts

Based on the io_margins provided the die area, if none provided the die and core will overlap.

The rectilinear site array.

Rectilinear power mesh and Power rings sturcture.

Outline aware port placement.

To report the constraints please use the **report_mpc_rectilinear_outline** command.

To remove the constraint please use the **-reset** option.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to specify the rectilinear outline.

```
prompt> set_mpc_rectilinear_outline \
-coordinates {500 500 800 500 800 \
               1000 1000 1000 1000 2000 800 2000 800 3000 \
               500 3000 500 2000 0 2000 0 1000 500 1000}

prompt> report_mpc_rectilinear_outline
```

set_mpc_ring_options

Specifies the constraints for ring generation around cores, macros, macro arrays, and designs in the floorplan in the flows of the **create_placement**, **physopt**, and **compile_physical** commands with the **-mpc** option.

SYNTAX

```
int set_mpc_ring_options
[-name name]
[-reset] | [-layer layer_name -type width width]
[-offset offset]
[-sides {top | left | right | bottom}]
[-layer ]
```

Data Types

<i>name</i>	string
<i>layer_name</i>	string
<i>width</i>	float
<i>offset</i>	float

ARGUMENTS

-name *name*
Specifies a unique name for the ring. This option is used to create the name of the pnet. The default is for the tool to provide a name.

-reset
Removes the attributes set by previous uses of the **set_mpc_pnet_options** command. If you do not use the **-reset** option, then the **-layer**, **-type**, and **-width** options are required.

-type {pwr | gnd}
Defines the type of pnet as either **pwr** (for power) or **gnd** (for ground). This option is required if you do not use the **-reset** option. The default is for the tool to select a type.

-width *width*
Specifies the width of the ring's strip. This option is required if you do not use the **-reset** option. The default is for the tool to select a width.

-offset *offset*
Specifies the distance, from the starting side, from the edge of the object around which the ring is made and the center of the ring. The default is for the tool to select an offset.

-sides {top | left | right | bottom}
Specifies the sides around the ring. The default is to use all sides.

-layer
Specifies the name of the metal layer in which the macro ring is to be drawn. This name is defined in the Synopsys physical library (.plib). This option

is required if you do not use the **-reset** option. The default is for the tool to select a layer.

DESCRIPTION

This command specifies the ring options to be used to create power and ground rings around cores, macros, macro arrays, or designs designated by using the the **create_placement**, **physopt**, and **compile_physical** commands when they specify the **-mpc** option. You should issue these commands after the design and physical libraries are loaded.

During the flow, the options are read and the trunks are drawn based on the options provided. After the ring pnets are generated, you can view them by using the **report_net** command with the **-only_physical** option.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to specify options for a ring on the metal4 layer using the widths and pitch around all sides of the core.

```
prompt> set_mpc_ring_option -layer Metal4 -name ring \
    -width 3.00 -type gnd -offset 5.00 \
    -sides {TOP LEFT RIGHT BOTTOM} [current_design]
```

```

set_mtcmos_pna_strategy

Sets options for power network synthesis (PNS) and power network analysis (PNA), when exploring, replacing, and optimizing MTCMOS cell size. These settings are not persistent in the Milkyway database.

SYNTAX

```
status set_mtcmos_pna_strategy
[-reset]
[-power_budget budget]
[-voltage_supply voltage_supply]
[-lowest_voltage_drop]
[-target_voltage_drop target_voltage]
[-pad_lib_cell pad_names]
[-read_pad_cell_file cell_file]
[-read_pad_lib_cell_file lib_cell_file]
[-use_pins_as_pads]
[-use_strap_ends_as_pads]
[-create_virtual_rails layer_names]
[-synthesise_voltage_areas ]
[-disable_snap_to_row_and_tile]
[-relative_to_voltage_area]
[-pattern {normal | stagger}]
[-voltage_areas list]
```

Data Types

<i>budget</i>	float
<i>voltage_supply</i>	float
<i>target_voltage</i>	float
<i>pad_names</i>	string
<i>cell_file</i>	string
<i>lib_cell_file</i>	string
<i>layer_names</i>	string

ARGUMENTS

```
-reset
    Reset the specified strategy value. If no strategy name is specified, all the
    strategy values will be reset.

-power_budget budget
    Specifies a total power budget to perform constraint-driven power network
    analysis and power net synthesis. The power budget is divided among the
    instances according to their size. The power unit is in milliwatts. For hard
    macros or standard cells, the power budget is computed based on the percentage
    of the total area. For a hierarchical block, the power budget is computed
    based on the sum of all the cells and blocks inside it. The default is 1000.

-voltage_supply voltage_supply
    Specifies the voltage of the net you want analyzed or synthesized. The power
    pads. The voltage unit is volts. The default is 1.5.
```

-lowest_voltage_drop
Specifies the lowest IR drop option if you want to direct the synthesize engine to synthesize a power plan or pad that would give the lowest possible IR drop value based on user-defined constraints. Default is false.

-target_voltage_drop target_voltage
Specifies a target IR drop value. Default value is 10% of the power pad voltage.

-read_pad_cell_file cell_file
Specify the pad cell file name. Default is null.
The format is: cell_name net_name (The net_name is optional.)
For example, VDD1 VDD
Note:
If the net name is not specified, the command assumes that the specified pad cell is used for both power and ground nets.

-read_pad_lib_cell_file lib_cell_file
Specify the pad lib cell reference file name. Default is null.
The format is: lib_cell net (The net is optional.)
For example, VDD.FRAM VDD
Note:
If the net name is not specified, the command assumes that the specified pad lib cell is used for both power and ground nets.

-use_pins_as_pads
Treats pins as pads in block level design. Default is false.

-use_strap_ends_as_pads
Uses the ends of straps as pads for block level design that has no pins or pads. Default is false.

-create_virtual_rails layer_names
During the floorplanning stages, metal 1 straps for the standard cell pin connections are usually not available. Power network analysis uses this option to create virtual pseudo straps that represent the metal 1 straps for the standard cell pin connections. During power planning, it then analyzes the IR (voltage) drop and electromigration to predict what the effects might be when the metal 1 straps are available. Creates pseudo horizontal straps with specified layers for standard cell pin connections based on the row information in the database. Default is null.

-synthesize_voltage_areas voltage_area_list
Specify the voltage areas need be synthesized in PNS.

-disable_snap_to_row_and_tile
Disable snap MTCMOS cells to row when placement.

-relative_to_voltage_area
Coordinates are specified relative to lower left corner of voltage area's bbox.

-pattern {normal | stagger}
Pattern used for header/footer cell placement.

DESCRIPTION

Sets parameters of power network synthesis (PNS) and power network analysis (PNA), when exploring, replacing, optimizing MT莫斯 cell size. These settings are not persistent in the Milkyway database. PNA and PNS operations are used in high-level commands such as `explore_header_footer` and `replace_header_footer`. This command is used to set the options needed to control the operations of PNA and PNS when running the high-level commands.

Options `-read_pad_cell_file`, `-lowest_voltage_drop`, `-target_voltage_drop`, `-use_strap_ends_as_pads`, `-synthesize_voltage_areas` only work with power network synthesis related operations. The rest options work for power network synthesis and analysis related operations.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example set use strap ends as pads, and specify 50 milliwatts power budget, 0.5 volts supply when PNA & PNS.

```
prompt> set_mtcmos_pna_strategy \
      -power_budget 50 \
      -voltage_supply 0.5 \
      -use_strap_ends_as_pads
```

SEE ALSO

```
analyze_fp_rail(2)
synthesize_fp_rail(2)
report_mtcmos_pna_strategy(2)
```

set_multicycle_path

Modifies the single-cycle timing relationship of a constrained path.

SYNTAX

```
integer set_multicycle_path
path_multiplier
[-rise | -fall]
[-setup | -hold]
[-start | -end]
[-from from_list
 | -rise_from rise_from_list
 | -fall_from fall_from_list]
[-through through_list]
[-rise_through rise_through_list]
[-fall_through fall_through_list]
[-to to_list
 | -rise_to rise_to_list
 | -fall_to fall_to_list]
[-reset_path]
```

Data Types

path_multiplier	integer
from_list	list
rise_from_list	list
fall_from_list	list
through_list	list
rise_through_list	list
fall_through_list	list
to_list	list
rise_to_list	list
fall_to_list	list

ARGUMENTS

path_multiplier

Specifies the number of cycles that the data path must have for setup or hold relative to the startpoint or endpoint clock before data is required at the endpoint. When used with **-setup**, this value is applied to setup path calculations. When used with **-hold**, this value is applied to hold path calculations. If neither **-hold** nor **-setup** are specified, *path_multiplier* is used for setup, and 0 is used for hold. Changing the multiplier for setup also affects the hold check.

-rise

Specifies that rising path delays are affected by *path_multiplier*. The default is that both rising and falling delays are affected. Rise refers to a rising value at the path endpoint.

-fall

Specifies that falling path delays are affected by *path_multiplier*. The

set_multicycle_path

2490

default is that both rising and falling delays are affected. Fall refers to a falling value at the path endpoint.

-setup

Specifies that *path_multiplier* is used for setup calculations.

-hold

Specifies that *path_multiplier* is used for hold calculations.

-start | -end

Specifies whether the multicycle information is relative to the period of the start clock or the end clock. These options are only needed for multifrequency designs; otherwise start and end are equivalent. The start clock is the clock source related to the register or primary input at the path startpoint. The end clock is the clock source related to the register or primary output at the path endpoint. The default is to move the setup check relative to the end clock, and the hold check relative to the start clock. A setup multiplier of 2 with **-end** moves the relation forward one cycle of the end clock. A setup multiplier of 2 with **-start** moves the relation backward one cycle of the start clock. A hold multiplier of 1 with **-start** moves the relation forward one cycle of the start clock. A hold multiplier of 1 with **-end** moves the relation backward one cycle of the end clock.

-from from_list

Lists the names of clocks, ports, pins, or cells to use to find path startpoints. If a clock is specified, all registers and primary inputs related to that clock are used as path startpoints. If a cell is specified a cell, one path startpoint on that cell is affected.

-rise_from rise_from_list

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from fall_from_list

Same as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through through_list

Lists the path throughpoints (port, pin, or leaf cell names) of the current design. The multicycle values apply only to paths that pass through one of the points in the *through_list*. If more than one object is included, the objects must be enclosed either in double quotation marks ("") or in braces ({}). If you specify the **-through** option multiple times, the multicycle values apply to paths that pass through a member of each *through_list* in the order the lists were given. The path must first pass through a member of the first *through_list*, then through a member of the second list, and so on for every through list specified. If the **-through** option is used in combination with the **-from** or **-to** options, the multicycle values apply only if the **-from**

or **-to** conditions are satisfied and the **-through** conditions are satisfied.

-rise_through *rise_through_list*

Same as the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than once in a single command invocation as with the **-through** option.

-fall_through *fall_through_list*

Same as the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than once in a single command invocation as with the **-through** option.

-to *to_list*

Lists the names of clocks, ports, pins or cells to use to find path endpoints. If a clock is specified, all registers and primary outputs related to that clock are used as path endpoints. If a cell is specified, one path endpoint on that cell is affected.

-rise_to *rise_to_list*

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to *fall_to_list*

Same as the **-to** option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-reset_path

Removes existing point-to-point exception information on the specified paths. When used only with **-to**, all paths leading to the specified endpoints are reset. When used only with **-from**, all paths leading from the specified startpoints are reset. When used with **-from** and **-to**, only paths between those points are reset. Only information of the same rise/fall, setup/hold type is reset. This is equivalent to using the **reset_path** command with similar arguments before issuing **set_multicycle_path**.

DESCRIPTION

The **set_multicycle_path** command specifies that designated timing paths in the current design have nondefault setup or hold relations.

The synthesis timing engine applies certain rules to determine single-cycle timing relationships for paths between clocked elements. The rules are based on active edges. For flip-flops, a single active edge both launches and captures data. For latches, the open edge is used to launch data, and the close edge is used to latch data.

The setup check ensures that the correct data signal is available on destination registers in time to be properly latched.

The rule for setup is that for multifrequency designs, there can be multiple setup relations between two clocks. For every latch edge of the destination clock, find the nearest launch edge which precedes each capture edge. The smallest difference of (setup_latch_edge - setup_launch_edge) determines the maximum delay requirement for this path.

This is known as single-cycle setup. You can override this default relationship using **set_multicycle_path** or **set_max_delay**. You can apply these commands to clocks, pins, ports, or cells. For example, setting the setup path multiplier to 2 with the **set_multicycle_path** command delays the latch edge one clock pulse. Changing the setup multiplier also affects the default hold check.

The hold check verifies the following items:

- Data from the source clock edge that follows the setup launch edge must not be latched by the setup latch edge.
- Data from the setup launch edge must not be latched by the destination clock edge that precedes the setup latch edge.

The hold check is determined relative to each valid setup relationship, after applying multicycle path multipliers. The most restrictive (largest) difference of (hold_latch_edge - hold_launch_edge) is used as a minimum delay requirement for the path.

The hold relation is conservative. In some cases you might need to override the default hold relation. For multifrequency designs, it is more straightforward to use the **set_min_delay** command to override the default instead of using **set_multicycle_path -hold**.

Setting *path_multiplier* for setup moves the setup check in time by an integer number of active edges. For example, specifying *path_multiplier* of 2 for setup implies a 2 cycle data path.

Most often, the setup check is moved relative to the end clock. This move changes the data latch time at the path endpoint. In multifrequency designs, use the following command to move the data launch time backward:

set_multicycle_path -setup -start

To move the hold relation relative to the end clock use the command
set_multicycle_path -hold -end

If you do not specify **-setup** or **-hold**, the setup relation is set to *path_multiplier* and the hold relation is set to 0.

If you specify **-setup**, the setup multiplier is set to *path_multiplier*. The hold multiplier is unaffected.

If you specify **-hold**, the hold multiplier is set to *path_multiplier*. The setup multiplier is unaffected.

There are separate setup and hold multipliers for rise and fall. In most cases, these are set to the same value. You can use the **-rise** or **-fall** options to apply different values.

The **set_multicycle_path** command is a point-to-point timing exception command. If a path satisfies multiple timing exceptions, the following rules are used in order to determine which exceptions take effect. Rules referring to **-from** apply equally to **-rise_from** and **-fall_from**, and similarly for the rise and fall options of **-through** and **-to**.

- Two **group_path** commands can conflict with each other, but a **group_path** exception alone does not conflict with another type of exception. So the remaining rules apply for two **group_path** exceptions, or two non-**group_path** exceptions.
- If both exceptions are **set_false_paths**, there is no conflict.
- If one exception is a **set_max_delay** and the other is **set_min_delay**, there is no conflict.
- If one exception is a **set_multicycle_path -hold** and the other is **set_multicycle_path -setup**, there is no conflict.
- If one exception is a **set_false_path** and the other is not, the **set_false_path** takes precedence.
- If one exception is a **set_max_delay** and the other is not, the **set_max_delay** takes precedence.
- If one exception is a **set_min_delay** and the other is not, the **set_min_delay** takes precedence.
- If one exception has a **-from** pin or **-from** cell and the other does not, the former takes precedence.
- If one exception has a **-to** pin or **-to** cell and the other does not, the former takes precedence.
- If one exception has any **-through** points and the other does not, the former takes precedence.
- If one exception has a **-from** clock and the other does not, the former takes precedence.
- If one exception has a **-to** clock and the other does not, the former takes precedence.
- The exception with the more restrictive constraint then takes precedence. For **set_max_delay** and **set_multicycle_path -setup**, this is the constraint with the lower value. For **set_min_delay** and **set_multicycle_path -hold**, it is the constraint with the higher value.

To undo a **set_multicycle_path** command, use **reset_path** or **reset_design**.

Use **set_false_path** to disable setup or hold calculations for paths.

Use **report_timing_requirements** to list the point-to-point exceptions on a design.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets all paths between latch1b and latch2d to 2 cycle paths for setup. Hold is measured at the previous edge of the clock at latch2d.

```
prompt> set_multicycle_path 2 -from {latch1b} -to {latch2d}
```

The following example moves the hold check to the preceding edge of the start clock:

```
prompt> set_multicycle_path -1 -from {latch1b} -to {latch2d}
```

The following example is a two-phase level-sensitive design, where the designer expects paths from phi1 to phi1 to be zero cycles:

```
prompt> set_multicycle_path 0 -from phi1 -to phi1
```

The following example uses **-start** to specify a 3-cycle path relative to the clock at the path startpoint. Clock sources are specified, affecting all sequential elements clocked by that clock, or ports with input or output delay relative to that clock.

```
prompt> set_multicycle_path 3 -start -from {clk50mhz} -to {clk10mhz}
```

The following example affects all paths that pass first through the U1 or U2 cell and later pass through the U3 cell. The path resulting in a rise transition at an endpoint is constrained to 2 cycles, but falling paths are constrained to 1 cycle.

```
prompt> set_multicycle_path 2 -rise -through {U1, U2} -through {U3}
```

```
prompt> set_multicycle_path 1 -fall -through {U1, U2} -through {U3}
```

The following multifrequency example shows a 20ns clock to a 10ns clock, with a multicycle path of 2. Assume a path from ff1 (clocked by clk20) to ff2 (clocked by clk10).

```
prompt> create_clock -period 20 -waveform {0 10} clk20
```

```
prompt> create_clock -period 10 -waveform {0 5} clk10
```

```
prompt> set_multicycle_path 2 -setup -from ff1/CP -to ff2/D
```

The single-cycle setup relation is from the CLK1 edge at 0ns to the CLK2 edge at 10ns. With the multicycle path, the setup relation is now 20ns (from the CLK1 edge at 0ns to CLK2 edge at 20ns). The hold relations are determined according to that setup relation.

- Data from the source clock edge that follows the setup launch edge must not be latched by the setup latch edge. This implies a hold relation of 0ns (from CLK1 edge at 20ns to CLK2 edge at 20ns).

- Data from the setup launch edge must not be latched by the destination clock edge that precedes the setup latch edge. This implies a hold relation of 10ns (from CLK1 edge at 0ns to CLK2 edge at 10ns).

The most restrictive (largest) hold relation is used, so the minimum delay requirement for this path is 10ns. This is a conservative check that might not apply to certain designs. Often you know that the destination register is disabled for the clock edge at 10ns. You can modify this default hold relation with the following command to get a 0ns requirement:

```
prompt> set_min_delay 0 -from ff1/CP -to ff2/D
```

However, an easier approach is to use the following command:

```
prompt> set_multicycle_path 1 -hold -end -from ff1/CP -to ff2/D
```

SEE ALSO

```

set_mw_lib_reference

Sets the reference library for the Milkyway library.

SYNTAX

```
status_value set_mw_lib_reference
[-mw_reference_library lib_list]
[-reference_control_file file_name]
libName
```

Data Types

<i>lib_list</i>	string
<i>file_name</i>	string
<i>libName</i>	string

ARGUMENTS

-mw_reference_library *lib_list*
Specifies a list of libraries to be set as reference libraries for the Milkyway library.
This argument and **-reference_control_file** are mutually exclusive.

-reference_control_file *file_name*
Specifies a reference control file containing information to set the reference libraries for the Milkyway library.
This argument and **-mw_reference_library** are mutually exclusive.

libName
Specifies the Milkyway library to be worked on.

DESCRIPTION

Sets or changes the reference libraries for the Milkyway library. The Milkyway library being updated must be closed for the command to work correctly. The **-reference_control_file** and **-mw_reference_library** options are mutually exclusive, and at least one of the two must be specified.

A status indicating success or failure is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the reference libraries with a list:

```
prompt> set_mw_lib_reference -mw_reference_library {./lib/ref1 ./lib/ref2} design
```

SEE ALSO

`create_mw_lib(2)`
`set_mw_technology_file(2)`

set_mw_technology_file

Sets the technology file of the Milkyway library.

SYNTAX

```
status_value set_mw_technology_file
[-technology tech_file]
[-plib plib_file]
libName
```

Data Types

<i>tech_file</i>	string
<i>plib_file</i>	string
<i>libName</i>	string

ARGUMENTS

-technology *tech_file*

Specifies a new technology file to use with the Milkyway library. The old technology information is completely replaced. Ensure that the new technology information is compatible, or else you must rebuild or recreate the Milkyway library accordingly.

-plib *plib_file*

Specifies a new plib file to use with the Milkyway library. If the plib file is an incremental plib file , it will load the technology file in plib incrementally to update library technology. If it is a complete technology plib file, library technology info will be replaced completely. Ensure that the new technology information is compatible, or else you must rebuild or recreate the Milkyway library accordingly.

libName

Specifies the Milkyway library to be updated. The value of *mw_lib* must be a valid library name.

DESCRIPTION

This command sets the technology file for a Milkyway library.

The command returns a status indicating success or failure.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the technology file of the library design to *new.tf*:

```
prompt> set_mw_technology_file -technology new.tf design  
1
```

SEE ALSO

`close_mw_lib(2)`
`copy_mw_lib(2)`
`create_mw_lib(2)`
`current_mw_lib(2)`
`open_mw_lib(2)`
`rename_mw_lib(2)`
`set_mw_lib_reference(2)`
`write_mw_lib_files(2)`

set_name

Changes the name of the specified netlist object.

SYNTAX

```
status set_name
-type net | port | cell
object
-name local_name
```

Data Types

<i>object</i>	collection
<i>local_name</i>	string

ARGUMENTS

```
-type net | port | cell
    Specifies if the given object is a net, a hierarchical port, or a leaf cell
    instance.

object
    Specifies the single netlist object on which the set_name command is applied.
    object can be a single object collection returned by a query command, such
    as get_nets, or a netlist object name string.

-name local_name
    Specifies the new local name. It is the name local to the parent hierarchical
    module.
```

DESCRIPTION

Changes the name that is local to the parent hierarchical module.

The **set_name** command changes the local names of nets, ports, and cells in a design. A netlist object name can consist of full hierarchical path to the object and the **set_name** command does not change this hierarchical path information.

EXAMPLES

The following example uses **set_name** to change the name of net M1/N1 to M1/N2 in the M1 hierarchical cell by changing its local name from N1 to N2:

```
prompt> set_name -type net M1/N1 -name N2
prompt> get_nets M1/N2
```

The following example uses **set_name** to change the name of the leaf cell M1/C1 to M1/C2 in the M1 hierarchical cell by changing its local name from C1 to C2:

```
prompt> set_name -type cell [get_cells M1/C1] -name C2
```

```
prompt> get_cells M1/*
```

SEE ALSO

```
change_names(2)
define_name_rules(2)
report_name_rules(2)
report_names(2)
default_name_rules(3)
```

set_net_aggressors

Sets the aggressor nets for a victim net.

SYNTAX

```
status set_net_aggressors
-victim_net net
-aggressor_nets collection_of_nets
```

Data Types

collection_of_nets list

ARGUMENTS

```
-victim_net net
            Specified a victim net.

-aggressor_nets collection_of_nets
            Specified one or multiple aggressor nets
```

DESCRIPTION

Specified a victim net and its associated aggressor nets. This information will be used during the routing stage to minimize crosstalk effect.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example is to set all nets, which are initialized with "NET_INV" and "OUT", to be aggressor nets for a victim net, NET_ANTENNA.

```
prompt> set_net_aggressors -victim_net NET_ANTENNA -
aggressor_nets {NET_INV* OUT*}
```

SEE ALSO

set_net_routing_layer_constraints

Assigns routing layer constraints to specific nets.

SYNTAX

```
int set_net_routing_layer_constraints  
list_of_nets  
-min_layer_name minimum_routing_layer_name  
-max_layer_name maximum_routing_layer_name
```

ARGUMENTS

list_of_nets
Lists the net names for which the routing layer constraints are applied.

-min_layer_name minimum_routing_layer_name
Specifies the minimum routing layer name.

-max_layer_name maximum_routing_layer_name
Specifies the maximum routing layer name.

DESCRIPTION

Assigns routing layer constraints to specific nets. By specifying this rule, Astro router will take the constraints into account.

The routing layer names you specify must exist in physical library as well as in the design and the maximum routing layer must be on the top of minimum routing layer.

If the net has already had routing layer constraints set earlier, we will give a warning message and will overwrite the existing routing layer constraints.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example assigns the routing layer constraints to the net named *netA*.

```
prompt> set_net_routing_layer_constraints {netA}\n-min_layer_name metal1 -max_layer_name metal3
```

SEE ALSO

`report_net_routing_layer_constraints(2)`
`remove_net_routing_layer_constraints(2)`

set_net_routing_rule

Assigns a nondefault or default routing rule to specific nets.

SYNTAX

```
integer set_net_routing_rule
    -rule rule_name
    list_of_nets
    [-timing_driven_spacing]
    [-reroute normal | minorchange | freeze]
    [-top_layer_probe AnyPort | OutPort | AllPort]
```

Data Types

<i>rule_name</i>	string
<i>list_of_nets</i>	string

ARGUMENTS

-rule *rule_name*
Specifies the name of the routing rule to be assigned. The *rule_name* can be either a name of an existing nondefault rule or a keyword *-default-*, which means that you must assign the default routing.

list_of_nets
Lists the net names for which a routing rule is assigned.

DESCRIPTION

This command assigns a nondefault or default routing rule to specific nets. Nondefault rules are defined in the physical library or by using the **define_routing_rule** command and can have associated user-defined width and spacing rules and via types. These rules govern nondefault wiring such as the wide wires and vias that are typically used for clock signals and other sensitive signals.

Library-specific rules are defined in the physical library and stored in the

If nondefault routing rules are not defined in the physical library provided with the design database, you can define them in a separate .plib file that can be updated into the existing .pdb file by using the **update_lib** command. For more information about the **update_lib** command, see the man page.

You can define design-specific rules by using the **define_routing_rule** command and storing them in the design .db file.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example, assigns a nondefault rule named *WideMetal* to a net named *B_CLK*.

```
prompt> set_net_routing_rule {B_CLK} -rule WideMetal
```

SEE ALSO

`update_lib(2)`
`define_routing_rule(2)`
`report_routing_rules(2)`

set_object_boundary

Sets the boundary of a set of objects to a bounding box or a list of points.

SYNTAX

```
status set_object_boundary
{-bbox rect | -boundary boundary}
[-keep_placement]
[-keep_pad_to_core_distance]
[-ignore_fixed]
objects
```

Data Types

<i>rect</i>	x1 y1 x2 y2
<i>objects</i>	collection

ARGUMENTS

-bbox rect

Specifies the bounding box to use as the boundary.

-boundary boundary}

Specifies the list of points to use as the boundary.

Note: There must be at least four points.

-keep_placement

This option is effective only when applied to the core or the die. It will be ignored if applied on any other object.

Cells in the core and IO pad cells are re-placed if necessary. The relative positions of the cells are not guaranteed to be preserved, although an attempt will be made to preserve them as much as possible. Furthermore, the output of the re-placement is not legalized. The user needs to explicitly legalize the placement using `legalize_placement`.

The default is **false**.

-keep_pad_to_core_distance

This option is effective only when applied to the core or the die. It will be ignored if applied on any other object.

This maintains the distance between the core and the pad cells and by implication the distance between the core and the die, thus forcing changes to the core and the die to be made in tandem with each other. If pad cells are absent then the core-to-die distance will still be maintained.

The default is **false**.

-ignore_fixed

Normally fixed objects can not have their boundary set. If this flag is supplied then fixed objects will also be changed.

objects

Specifies the objects to have their boundary set.

DESCRIPTION

This command sets the boundary of one or more objects to the specified bounding box or set rectilinear points.

Only objects which can be resized can have their bounding box set.

Only objects which can be rectilinear can have a boundary of more than four points.

See `get_edit_property(2)` man page for details on which objects can be resized and which objects can be rectilinear.

NOTES

Fixed objects will not have their boundary set unless `-ignore_fixed` is specified.

Snapping is done automatically using global snap settings.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples set the boundary of the selected object to (0 0) (100 100).

```
prompt> set_object_boundary -bbox {0 0 100 100} [get_selection]
```

The following examples set the boundary of the selected object to a L shape.

```
prompt> set_object_boundary \
    -boundary {{0 0} {100 0} {100 50} {50 50} {50 100} {0 100}} \
    [get_selection]
```

SEE ALSO

`set_object_shape(2)`

set_object_fixed_edit

Sets the fixed state for one or more objects.

SYNTAX

```
status set_object_fixed_edit
objects
fixed
```

ARGUMENTS

objects
List of objects to set fixed for

fixed
List of one or more Boolean fixed flags

DESCRIPTION

Set the fixed state for the supplied objects. Each object is set to the value of the flag at the corresponding position in the fixed list. If the fixed list is shorter than the object list the last value in the fixed list is propagated to achieve the required size. If the fixed list is longer than the object list the extra values are silently ignored.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example fixes all selected objects

```
> set_object_fixed_edit [get_selection] 1
```

SEE ALSO

`get_object_fixed_edit(2)`

set_object_shape

Sets the shape of a set of objects to one of the standard rectilinear shapes.

Only objects which can be resized can be set to a "rect" shape.

Only objects which can be rectilinear can be set to a "l", "t", "u" or "cross" shape.

See `get_edit_property(2)` man page for details on which objects can be resized and which objects can be rectilinear.

SYNTAX

```
status set_object_shape
-shape {rect | l | t | u | cross}
-lengths real_list
[{-utilization real
  | -area real
  | -keep_area}]
[-rotate {0 | 90 | 180 | 270}]
[-keep_placement]
[-keep_pad_to_core_distance]
[-ignore_fixed]
objects
```

Data Types

objects collection

ARGUMENTS

`-shape {rect | l | t | u | cross}`

Specifies the shape to use.

This is either a Rectangular, L, T, U or Cross shape.

`-lengths real_list`

Specifies the absolute lengths in microns or length ratios of the sides of the shape.

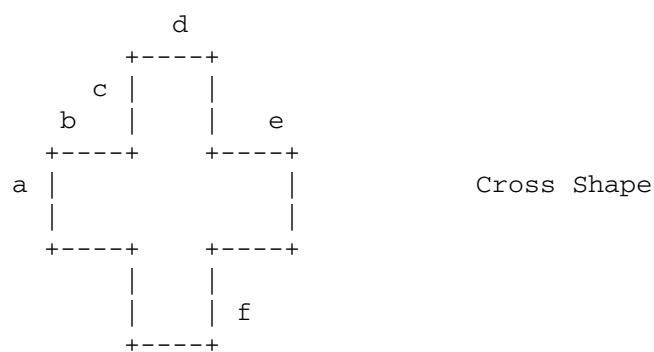

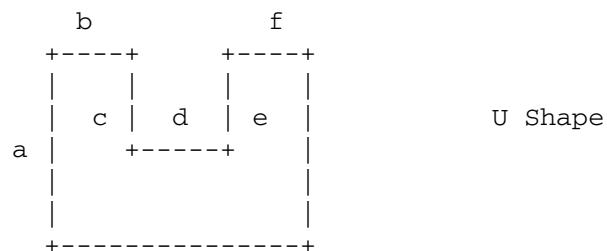

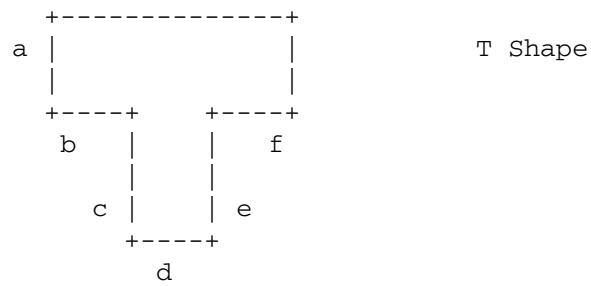

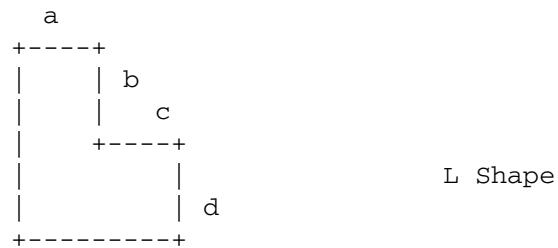

Absolute lengths are assumed unless one of `-utilization`, `-area` or `-keep_area` is specified.

If length ratios are specified then the resultant shape will have sides with the corresponding ratios e.g. if the ratios are all one then all lengths will be the same. If one ratio is two and the others are one then that side will be twice as long as the others.

Each shape requires a different number of values as described below:

&. rect	2
&. l	4
&. t	6
&. u	6
&. cross	6

See diagrams below for the meaning of parameter values for each shape (a is first value, b is second value etc.):

```
-utilization real
    Specifies that the new shape should have the specified utilization.
    Utilization is defined as physical_area divided by placement area and is most
    commonly used for plan groups and utilization where the enclosed area can be
    larger than the associated child physical objects.
    Utilization must be positive and non-zero.
Note: this implies that lengths are ratios and not absolute values.
    The default is 0.7.
```

```
-area real
    Specifies that the new shape should have the specified area.
Note: this implies that lengths are ratios and not absolute values.
    The default is 1.0.
```

```
-keep_area
    Specifies that the new shape should have the same area as the object current
    has.
Note: this implies that lengths are ratios and not absolute values.
```

```
-rotate {0 | 90 | 180 | 270}
    Specifies that the base shape is geometrically rotated from the default
    orientation (See diagram above) before being applied to the object.
Note: this option cannot be used with -shape rect
Note: 0 is the default value so this option only needs to be specified for
    90, 180 and 270 rotation.
```

```
-keep_placement
    This option is effective only when applied to the core or the die. It will
    be ignored if applied on any other object.
    Cells in the core and IO pad cells are re-placed if necessary. The relative
    positions of the cells are not guaranteed to be preserved, although an attempt
    will be made to preserve them as much as possible. Furthermore, the output
    of the re-placement is not legalized. The user needs to explicitly legalize
    the placement using legalize_placement.
    The default is false.
```

```
-keep_pad_to_core_distance
    This option is effective only when applied to the core or the die. It will
    be ignored if applied on any other object.
    This maintains the distance between the core and the pad cells and by
    implication the distance between the core and the die, thus forcing changes
    to the core and the die to be made in tandem with each other. If pad cells
    are absent then the core-to-die distance will still be maintained.
    The default is false.
```

```
-ignore_fixed
    Normally fixed objects can not have their shape set.
    If this flag is supplied then fixed objects will also be changed.
```

```
objects
    list of objects for which the boundary shape will be set.
```

DESCRIPTION

This command sets the shape of the boundary of one or more objects.

Only objects that can be resized can be set to a "rect" shape.

Only objects that can be rectilinear can be set to a "l", "t", "u" or "cross" shape.

See the `get_edit_property(2)` man page for details on which object types can be resized and which object types can be rectilinear.

NOTES

Snapping is done automatically using global snap settings.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the boundary of the selected objects to an L shape with all sides of equal length and a utilization of 0.7

```
> set_object_shape -shape l -params {1 1 1 1} -utilization 0.7 [get_selection]
```

SEE ALSO

`set_object_boundary(2)`

set_object_snap_type

Sets the snapping type for an object class.

SYNTAX

```
old_value set_object_snap_type
{-
class {soft_macro | plan_group | hard_macro | standard_cell | routing | shape | pin}
    | -enabled sbool}
[-
snap {litho | row | row_tile | mid_row | mid_row_tile | flip_chip | unit_tile | wir
etrack | halfwiretrack | user | none}]
```

ARGUMENTS

```
-class {soft_macro | plan_group | hard_macro | standard_cell | routing | shape | pin}
    Object class to set the snapping type for. One of:
        soft_macro      Soft Macro
        plan_group      Plan Group
        movebound       Movebound
        hard_macro      Hard Macro
        standard_cell   Standard Cell
        routing          Net shape, Via and Via Array
        shape            Polygon
        pin              Top Level Pin, Soft Macro Pin, Pin Guide
        rp_group         Relative Placement Group

-enabled sbool}
    Sets whether snapping is enabled or disabled for all objects.

-snap {litho | row | row_tile | mid_row | mid_row_tile | flip_chip | unit_tile |
wiretrack | halfwiretrack | user | none}
    Snap type. One of:
        litho           Design grid (also known as minimum grid)
        row             Row edge
        row_tile        Row edge and unit tile
        row_site        Row edge and placement site
        mid_row         Mid row (mostly for soft macro placement)
        mid_row_tile   Mid row and unit tile
        mid_row_site   Mid row and placement site
        flip_chip      Flip chip grid (for flip chips)
        unit_tile       Unit tile
        wiretrack       Wire track (for pins, wires, paths, and terminals)
        halfwiretrack  Mid wire track (for pins, wires, paths, and terminals)
        user            User grid

Note: setting the snap type to litho is equivalent to turning off snapping
for the specified object class.

The default snap types for the different object classes are as below:
    soft_macro      mid_row
    plan_group      mid_row
    movebound       row_site
    hard_macro      row
```

```
standard_cell row_site
routing        wiretrack
shape          litho
pin            wiretrack
rp_group       min_grid
```

RETURNS

old_value

The old snap value of the specified object class.
If -enabled is used, the value returned is the previous state of snap-enabling. For example, if snapping is currently disabled, **set_object_snap_type -enabled true** returns "0". This is because snapping was disabled prior to the invocation of the command -- it does not mean that the command has failed. If snapping is currently enabled, **set_object_snap_type -enabled true** returns "1".

DESCRIPTION

Sets the snapping type for an object class. All subsequent editing commands use this snap type to snap the position and geometry of the object.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies that all subsequent edits of hard macro objects will be snapped to the user grid:

```
rompt> set_object_snap_type -class hard_macro -snap user
```

The following disables all snapping:

```
rompt> set_object_snap_type -enabled false
```

SEE ALSO

```
move_objects(2)
resize_objects(2)
rotate_objects(2)
align_objects(2)
distribute_objects(2)
expand_objects(2)
flip_objects(2)
get_object_snap_type(2)
```

set_operand_isolation_scope

Specifies whether a design or instance should be included or excluded for operand isolation processing.

SYNTAX

```
status set_operand_isolation_scope
object_list
[true | false]
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of designs or instances for which operand isolation processing is to be enabled or disabled.

true | false

Specifies whether to enable (**true**) or disable (**false**) operand isolation processing for the *object_list*. The default value is **true**, which enables operand isolation processing.

DESCRIPTION

Use of the **set_operand_isolation_scope** command is not recommended. This feature will be obsolete in a future release. The **set_operand_isolation_scope** command sets an attribute on a list of designs or instances. This attribute controls whether or not an instance or top level of the current design will be processed during the operand isolation optimization phase.

When an attribute is specified for an instance as well as the corresponding design of that instance, the attribute value of the instance has higher priority. When the attribute is not specified on either the design or the instance, the behavior is inherited from the parent instance. The default value for the top level of the current design is **true**. By default, operand isolation processing is enabled for the entire design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example indicates that all instances of the design named *dsg* should be considered for processing during operand isolation:

```
set_operand_isolation_scope
2516
```

```
prompt> set_operand_isolation_scope [get_designs dsg]
```

This example specifies that the *U3/U5* instance should be excluded from operand isolation processing:

```
prompt> set_operand_isolation_scope [get_cells U3/U5] false
```

SEE ALSO

[do_operand_isolation\(3\)](#)

set_operating_conditions

Defines the operating conditions for the current design.

SYNTAX

```
int set_operating_conditions
[-analysis_type bc_wc | on_chip_variation]
[-min min_condition]
[-max max_condition]
[-min_library min_lib]
[-max_library max_lib]

[condition]
```

Data Types

<i>min_condition</i>	list
<i>max_condition</i>	list
<i>objects</i>	list
<i>condition</i>	list

ARGUMENTS

-analysis_type bc_wc | on_chip_variation

Specifies how to use the operating conditions. The **bc_wc** and **on_chip_variation** options are mutually exclusive; use only one per command. Specifying either **bc_wc** or **on_chip_variation** switches the design to min_max mode. The **bc_wc** value specifies that the min and max operating conditions are two extreme operating conditions. In the bc_wc analysis, setup violations are checked only for the maximum operating condition, and the hold violations are checked only for the minimum operating condition. The **on_chip_variation** value specifies that the minimum and maximum operating conditions represent, respectively, the lower and upper bounds of the maximum variation of operating conditions on the chip. All maximum path delays use the maximum operating condition, and all minimum path delays use the minimum operating condition.

-min *min_condition*

Specifies the operating condition to use for minimum delay analysis. If you do not specify an operating condition for minimum delay analysis, the tool uses the maximum operating condition. The **-min** option must be used with the **-max** option.

-max *max_condition*

Specifies the operating condition to use for maximum delay analysis.

-min_library *min_lib*

Specifies the library containing definitions of the operating conditions for minimum delay analysis. This is either a library name or a collection. The

tool selects the first library in the collection containing the definitions.

-max_library max_lib
 Specifies the library containing definitions of the operating conditions for maximum delay analysis. This is either a library name or a collection. The tool selects the first library in the collection containing the definitions.

-min_phys min_proc
 Specifies the name of the process resource to search for the resistance and capacitance values for minimum delay analysis. This option must be used in with the **-max_phys** option.

-max_phys max_proc
 Specifies the name of the process resource to search for the resistance and capacitance values for maximum delay analysis. This argument must be used with the **-min_phys** option.

-library lib
 Specifies the library containing definitions of the operating conditions for both maximum and minimum delay analysis. This is either a library name or a collection. The tool selects the first library in the collection containing the definitions.

-object_list objects
 Specifies the cells or ports on which to set operating conditions. If you do not use this option, operating conditions are set on the design. This option accepts both leaf cells and hierarchical blocks. This option is only available for Multi-Voltage features and require the appropriate license.

condition
 Specifies conditions that define environmental characteristics to use during maximum and minimum delay analysis.

DESCRIPTION

This command defines the operating conditions (or environmental characteristics) under which to time or optimize the current design. The operating conditions specified must be defined in lib or in one of the libraries in the link_library. A local_link_library set on the current design is added to the beginning of the link_library, before the link_library is searched. The order for a library search is as follows:

1. lib
2. **local_link_library**
3. **link_library**

If you do not specify any operating conditions for a design, the **compile** command searches in the first library of the link library for default operating conditions. If the library does not have default operating conditions, no operating conditions are used.

Operating conditions set by using the **-object_list** option override the operating

conditions set on design or higher levels of hierarchy.

To see the operating conditions that are defined for the current design, and to see which libraries the current design is linked to, use the **report_design** command. To see the operating conditions defined in the specified library, use the **report_lib** command.

To remove operating conditions from the current design, use **set_operating_conditions** without specifying any operating conditions, or use the **reset_design** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows an operating condition definition, as it appears in the source text of a library:

```
operating_conditions("BCCOM") {      process : 0.6 ;
    temperature : 20 ;
    voltage : 5.25 ;
    tree_type : "best_case_tree" ;
}
```

The name of this set of operating conditions is *BCCOM*. The parameters are defined as follows:

process

A floating-point number that represents the characteristics of a semiconductor manufacturing process.

temperature

A floating-point number that represents the temperature of the defined environment.

voltage

A floating-point number that defines the upper boundary of the voltage range in which the defined environment operates. The lower boundary is always 0.0.

tree_type

The interconnect model for the environment. The **compile** command uses the interconnect model to select a formula for calculating interconnect delays. Three models are available:

- *best_case_tree*, which assumes the net delay to be 0
- *worst_case_tree*, which uses the lumped RC model
- *balanced_tree*, in which all loads share the wire resistance evenly.

When process factor, operating temperature, and operating voltage deviate from their

nominal values, **compile** uses a linear model to compensate for the effect of deviations on such values as cell delays, input loads, and output drives. The nominal values used are defined in the same library that contains the definitions of the set of operating conditions.

The following example sets the operating conditions to *WCIND* if the link_library is *my_lib.db*, and the design does not have a local_link_library set. The library name for *my_lib.db* is *my_lib_core*.

```
prompt> set_operating_conditions WCIND
```

```
Using operating condition 'WCIND' found in library "my_lib_core".
```

In the following example, the BCIND values found in *other_lib.db* are used for minimum delay analysis, and WCIND values are used for maximum delay analysis. The library name for *other_lib.db* is *other_lib_core*.

```
prompt> set_operating_conditions -min BCIND -max WCIND \
-library other_lib_core
```

```
Using operating condition 'BCIND' found in library 'other_lib_core'.
```

```
Using operating condition 'WCIND' found in library 'other_lib_core'.
```

The following example shows how to remove operating conditions defined for the current design:

```
prompt> set_operating_conditions
```

SEE ALSO

```
report_lib(2)

set_local_link_library(2)
link_library(3)
```

set_opposite

Defines two input ports as logically opposite.

SYNTAX

```
int set_opposite
port1
port2
```

Data Types

```
port1      string
port2      string
```

ARGUMENTS

```
port1 port2
Input port names in the current design that are logically opposite.
```

DESCRIPTION

Defines two input ports in the current design as logically opposite. Use the command to eliminate redundant inverters and improve the quality of optimization. Inconsistencies in logical relations among ports are detected. It is an error to specify such an inconsistency using **set_opposite**.

Use the **reset_design** command to remove this property from a port.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets two input ports named "A" and "B" to be logically opposite.

```
prompt> set_opposite A B
```

SEE ALSO

```
reset_design(2)
set_equal(2)
current_design(3)
```

set_optimize_dft_options

Defines options for physical design-for-test (DFT) optimization.

SYNTAX

```
status set_optimize_dft_options
[-repartitioning_method none | single_directional | multi_directional | adaptive]
[-single_dir_option horizontal | vertical]
```

ARGUMENTS

-repartitioning_method none | single_directional | multi_directional | adaptive
Specifies the type of the scan chain repartition algorithm used in placement aware scan optimization.
If you specify 'none', no scan repartition will be done in optimize_dft.
If you specify 'single_directional', the traditional single-directional scan repartition algorithm will be employed. By default, the direction is Horizontal, and you can use the option '-single_dir_option' to specify the desired direction.
If you specify 'multi_directional', the multi-directional scan repartition algorithm will be employed. The multiple-directional one is designed to achieve better scan path total wire-length reduction efficiency, especially for the design with huge scan chain number.
If you specify 'adaptive', the scan repartition algorithm will be chosen adaptively according to the scan chain number for best scan wire-length reduction efficiency consideration. For the design with scan chain number no more than 20, the traditional single-directional scan repartition algorithm will be employed, otherwise, the multi-directional scan repartition algorithm will be used. If the single-directional algorithm is chosen, the partition direction is determined by the 'single_dir_option' setting.
The default value of this option is adaptive.

-single_dir_option horizontal | vertical
Specifies the desired direction of single directional scan repartition algorithm. The option only takes effect when the option '-repartitioning_method' is set with value of 'single_directional' or if 'adaptive' is used on a design with 20 or fewer scan chains. The default value of this option is 'horizontal'.

SEE ALSO

`optimize_dft(2)`
`report_optimize_dft_options(2)`

set_optimize_pre_cts_power_options

Specifies options for the **optimize_pre_cts_power** command.

SYNTAX

```
status set_optimize_pre_cts_power_options
[-default]
[-honor_dont_touch]
[-honor_size_only]
[-psyn_constraint_file file_name]
[-cts_constraint_file file_name]
[-split_clock_gates true | false]
```

Data Types

file_name string

ARGUMENTS

-default

Specifies the default options for **optimize_pre_cts_power**. All the options previously set will be reset to the default values.

-honor_dont_touch

By default, the **optimize_pre_cts_power** command can restructure integrated clock-gating (ICG) cells that have the **dont_touch** attribute. When you set this option, such ICGs will not be merged or removed. This option is effective only when you set **set_power_options -clock_gating true**.

-honor_size_only

By default, the **optimize_pre_cts_power** command can restructure integrated clock-gating (ICG) cells that have the **size_only** attribute. When you set this option, such ICGs will not be merged or removed. This option is effective only when you set **set_power_options -clock_gating true**.

-psyn_constraint_file *file_name*

Specifies the name of the file that contains the design constraints for physical synthesis. The specified file should be a valid tcl script that is to be sourced during physical synthesis or placement stage. If this constraint file is found, it will be sourced during physical synthesis stage by **optimize_pre_cts_power**.

-cts_constraint_file *file_name*

Specifies the name of the file that contains the design constraints for clock tree synthesis (CTS). The specified file should be a valid tcl script that is to be sourced during the CTS stage. If this constraint file is found, it will be sourced during the CTS stage by **optimize_pre_cts_power**.

-split_clock_gates true | false

Specifies whether to enable the **-split_clock_gates** option. When set to **true**, **split_clock_gates** is invoked after the initial (trial) clock tree synthesis. It optimizes the timing of the enable pins of clock gates and replicates the

clock gates that affect the worst negative slack (WNS) if they are driving clock buffer trees. Refer to **set_split_clock_gates_options** for more details. This option is set to **false** by default.

DESCRIPTION

The command sets the various strategy options for the **optimize_pre_cts_power** command. If any constraint file names of physical synthesis, clock tree synthesis (CTS), or both are specified, the files will be read in by **optimize_pre_cts_power**. Note that the constraints specified in any of the tcl files will be persistent in the design and thus can affect future operations on the design even after **optimize_pre_cts_power**. You should apply CTS constraints before running any CTS commands.

The **report_optimize_pre_cts_power_options** command reports the option values.

If you set **set_power_options -clock_gating to false** (the default) to disable clock-gating optimization, all the sub-options for clock-gating optimization will be ignored.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to set the options by using **set_optimize_pre_cts_power_options**.

```
prompt> set_power_options -clock_gating true
prompt> set_optimize_pre_cts_power_options -honor_dont_touch \
           -psyn_constraint_file psyn_sdc.tcl
prompt> optimize_pre_cts_power
```

SEE ALSO

optimize_pre_cts_power(2)
report_optimize_pre_cts_power_options(2)
set_split_clock_gates_options(2)

set_output_delay

Sets output delay on pins or output ports relative to a clock signal.

SYNTAX

```
int set_output_delay
delay_value
[-clock clock_name [-clock_fall] [-level_sensitive]]
[-network_latency_included]
[-source_latency_included]
[-rise]
[-fall]
[-max]
[-min]
[-add_delay]
[-group_path group_name]
port_pin_list
```

Data Types

<i>delay_value</i>	float
<i>clock_name</i>	string or collection
<i>group_name</i>	string
<i>port_pin_list</i>	list

ARGUMENTS

delay_value
Specifies the path delay. The *delay_value* must be in units consistent with the technology library used during optimization. The *delay_value* represents the amount of time that the signal is required before a clock edge. For maximum output delay, this usually represents a combinational path delay to a register plus the library setup time of that register. For minimum output delay, this value is usually the shortest path delay to a register minus the library hold time.

-clock *clock_name*
Specifies the clock to which the specified delay is related. If **-clock_fall** is used, **-clock** *clock_name* must be specified. If **-clock** is not specified, the delay is relative to time zero for combinational designs. For sequential designs, the delay is considered relative to a new clock with period determined by considering the sequential cells in the transitive fanout of each port.
The clock can be either a string or collection of one object.

-clock_fall
Specifies that the delay is relative to the falling edge of the clock. If **-clock** is specified, the default is the rising edge.

-level_sensitive
Specifies that the destination of the delay is a level-sensitive latch. This allows the tool to derive setup and hold relationship for paths to this port

as if it were a level-sensitive latch. If **-level_sensitive** is not used, the output delay is treated as if it were a path to a flip-flop.

-network_latency_included

Specifies that the clock network latency should not be added to the output delay value. If this option is not specified, the clock network latency of the related clock is added to the output delay value. It has no effect if the clock is propagated or the output delay is not specified with respect to any clock.

-source_latency_included

Specifies that the clock source latency should not be added to the output delay value. If this option is not specified, the clock source latency of the related clock is added to the output delay value. It has no effect if the output delay is not specified with respect to any clock.

-rise

Specifies that *delay_value* refers to a rising transition on specified ports of the current design. If neither **-rise** nor **-fall** is specified, then rising and falling delays are assumed to be equal.

-fall

Specifies that *delay_value* refers to a falling transition on specified ports of the current design. If neither **-rise** nor **-fall** is specified, then rising and falling delays are assumed to be equal.

-max

Specifies that *delay_value* refers to the longest path. If neither **-max** nor **-min** is specified, maximum and minimum output delays are assumed to be equal.

-min

Specifies that *delay_value* refers to the shortest path. If neither **-max** nor **-min** is specified, maximum and minimum output delays are assumed to be equal.

-add_delay

Specifies whether to add delay information to the existing output delay, or to overwrite. The **-add_delay** option enables you to capture information about multiple paths leading from an output port that are relative to different clocks or clock edges.

For example, the following command removes all other maximum rise output delay from **OUT1**, since **-add_delay** is not specified. Other output delay with a different clock or with **clock_fall** is removed.

```
prompt> set_output_delay 5.0 -max -rise -clock phi1 {OUT1}
```

In the following example, **-add_delay** is specified:

```
prompt> set_output_delay 5.0 -max -rise -clock phi1 \
           -add_delay {Z}
```

If there is an output maximum rise delay for **Z** relative to the clock **phi1** rising edge, the larger value is used. The smaller value does not result in critical timing for maximum delay. For minimum delay, the smaller value is used. If there is maximum rise output delay relative to a different clock or different edge of the same clock, it remains with the new delay.

-group_path group_name

Specifies that paths ending at the specified ports or pins are added into the named group. If the group does not already exist, it is created. This is

```
equivalent to specifying the following command in addition to  
set_output_delay:  
prompt> group_path -name group_name -to port_pin_list  
If -group_path is not specified, the existing path grouping is not changed.
```

port_pin_list

A list of output port or internal pin names in the current design to which *delay_value* is assigned. If more than one object is specified, the objects are enclosed in double quotation marks ("") or in braces ({}). If output delay is specified on a pin, the cell of the pin is set to size only to leave room for compile applying sizing on it.

DESCRIPTION

This command sets output path delay values for the current design. Used with the **set_load** and **set_driving_cell** commands, the input and output delays characterize the operating environment of the current design.

The **set_output_delay** command sets output path delays on output ports relative to a clock edge. Output ports are assumed to have no output delay unless specified. For inout (bidirectional) ports, you can specify the path delays for both input and output modes.

To describe a path delay to a level-sensitive latch, use the **-level_sensitive** option. If the latch is positive-enabled, set the output delay relative to the rising clock edge. If the latch is negative-enabled, set the output delay relative to the falling clock edge. If time is being borrowed at that latch, subtract that time borrowed from the path delay to the latch when determining output delay.

The **characterize** command automatically sets input and output delay, drive, and load values based on the environment of a cell instance.

The tool adds input delay to path delay for paths starting at primary inputs and output delay for paths ending at primary outputs.

The **-group_path** option modifies the path grouping. Path grouping affects the maximum delay cost function. The worst violator within each group adds to the cost. For optimization, grouping some paths separately may improve their delay cost, but it may also increase design area and compile time.

Use **report_port** to list output delays associated with ports. To list output delays of internal pins, use **report_design**. Use **report_path_group** to list the path groups which are defined.

Use **remove_output_delay** or **reset_design** to remove output delay values. To modify paths grouped with the **-group_path** option, use the **group_path** command to place the paths in another group or the default group.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets an output delay of 1.7 relative to the rising edge of CLK1 for all output ports in the design.

```
prompt> set_output_delay 1.7 -clock [get_clocks CLK1] \
[all_outputs]
```

The following example sets the input and output delays for the INOUT1 bidirectional port. The input signal arrives at INOUT1 2.5 units after the falling edge of CLK1. The output signal is required at INOUT1 at 1.4 units before the rising edge of CLK2.

```
prompt> set_input_delay 2.5 -clock CLK1 -clock_fall {INOUT1}

prompt> set_output_delay 1.4 -clock CLK2 {INOUT1}
```

In the following example there are three paths from the OUT1 output port. One path is relative to the rising edge of CLK1. Another path is relative to the falling edge of CLK1. The third path is relative to the falling edge of CLK2. The **-add_delay** option is used to indicate that new output delay information will not cause old information to be removed.

```
prompt> set_output_delay 2.2 -max -clock CLK1 \
-add_delay {OUT1}

prompt> set_output_delay 1.7 -max -clock CLK1 \
-clock_fall -add_delay {OUT1}

prompt> set_output_delay 4.3 -max -clock CLK2 \
-clock_fall -add_delay {OUT1}
```

The following example specifies two maximum delays and two minimum delays for the Z port using **-add_delay**. Since the information is relative to the same clock and clock edge, only the largest of the maximum values (5.0) and the smallest of the minimum values (1.1) are maintained. If **-add_delay** is not used, the new information overwrites the old information.

```
prompt> set_output_delay 3.4 -max -clock CLK1 \
-add_delay {Z}

prompt> set_output_delay 5.0 -max -clock CLK1 \
-add_delay {Z}

prompt> set_output_delay 1.1 -min -clock CLK1 \
-add_delay {Z}

prompt> set_output_delay 1.3 -min -clock CLK1 \
-add_delay {Z}
```

The following example uses the **-group_path** option to add ports into a named group. Without this option, paths to these ports are included in the CLK group.

```
prompt> set_output_delay 4.5 -max -clock CLK \
-group_path busA {busA[*]}
```

set_pad_physical_constraints

Sets physical constraints per pad instance.

SYNTAX

```
status set_pad_physical_constraints
-pad_name string pad_name objects
  | [-side side_number]
  [-order order_number]
  [-offset offset_distance]
  [-orientation reflect | optimizeReflect]
  [-min_left_iospace min_space_left]
  [-min_right_iospace min_space_right]
```

Data Types

<i>objects</i>	collection
<i>side_number</i>	integer
<i>order_number</i>	integer
<i>offset_distance</i>	float
<i>min_space_left</i>	float
<i>min_space_right</i>	float

ARGUMENTS

-pad_name *string*

Specifies the name of the pad cell to which the specified constraints apply. You can specify a single pad cell, which does not have to exist in the design. The constraint is stored in the database even though it might not get applied. In such cases, the constraint is automatically applied when a new pad with this name is added to the design.

This option and the *objects* argument are mutually exclusive. You must specify the pad cells by using one of these arguments.

objects

Specifies the pad cells to which the specified constraints apply. You can specify one or more pad cells that currently exist in the design. However, only one object is allowed if you use the **-order** option.

This argument and the **-pad_name** option are mutually exclusive. You must specify the pad cells by using one of these arguments.

-side *side_number*

Specifies the die edge on which the pad must reside. Pads are supported only with rectangular floorplans, so there are only four valid sides. The valid values for this option are

- * 0 (default - no side constraints)
- * 1 (left side constraint)
- * 2 (top side constraint)
- * 3 (right side constraint)
- * 4 (bottom side constraint)

The default is 0, which means that the pad does not have a side constraint.

```

-order order_number
    Specifies the placement order number for the pad. The placement order is a
    clockwise ordering constraint. This number must be a positive integer. The
    default is 0, which means that the pad does not have an ordering constraint.

-offset offset_distance
    Specifies the distance in microns that the pad must be offset from from the
    die edge on which it is placed. The specified value must be a positive
    floating point number.

-orientation reflect | optimizeReflect
    Specifies the lateral reflection mode. Valid values are:
    * reflect
        Reflects the pad instance about the axis through its center
        that is perpendicular to the edge on which the pad cell is
        sitting.
    * optimizeReflect
        Allows the tool to reflect only if area is optimized as a
        result.
    If you do not specify this option, no lateral reflection is done.

-min_left_iospace min_space_left
    Specifies the minimum spacing in microns to the next I/O pad on the left side.
    The default value is 0.

-min_right_iospace min_space_right
    Specifies the minimum spacing in microns to the next I/O pad on the right
    side. The default value is 0.

```

DESCRIPTION

Specifies physical design constraints on pads, such as location and offset between adjacent pads. The specified constraints are saved when the design is saved.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to specify physical constraints on a pad.

```
prompt> set_pad_physical_constraints -pad_name "uDFT3/uINP0" \
-side 1 -order 1 -offset 248.34
```

SEE ALSO

```

```
read_io_constraints(2)
```

set_parameter

Sets parameters for placement and routing operations.

SYNTAX

```
int set_parameter
-name name
-value value
[-module {route | groute | droute | trackAssign | ek | preroute | sr}]
[-type {{int | integer} | {real | float} | string}]
```

Data Types

name	string
value	integer

ARGUMENTS

```
-name name
    Specifies the name of the parameter to be set.

-value value
    Specifies the value of the parameter to be set.

-module {route | groute | droute | trackAssign | ek | preroute | sr}
    {route | groute | droute | trackAssign | ek | preroute | sr}
    Specifies the module for which you are setting a parameter. If this option
    is not specified, then the tool searches the parameters in all of the modules
    supported by the set_parameter command. The tool sets the value if exactly
    one match is found. If multiple modules have the same parameter name, use the
    -module option to uniquely identify the parameter.

-type {{int | integer} | {real | float} | string}
    Specifies the type of the parameter to be set. The three parameter types
    supported are integer, real, and string. If this option is not specified, the
    tool searches for the parameter and sets the value if exactly one match is
    found.
```

DESCRIPTION

The **set_parameter** command sets parameters for placement and routing operations. Use the **report_parameter** command to view a list of parameters, their values, and their definitions.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the *timingdriven* parameter to a value of 1:

```
prompt> set_parameter -name timingdriven -value 1
```

The following example sets the *timingdriven* parameter to an integer value of 1 in the **droute** module:

```
prompt> set_parameter -name timingdriven -value 1 -module droute \
          -type integer
```

SEE ALSO

insert_well_filler(2)
```

set_physical_signoff_options

Sets the environment setting for IC Validator (ICV) or Hercules before executing the **signoff_drc** or **signoff_metal_fill** command, and so on.

SYNTAX

```
status set_physical_signoff_options
[-default]
[-exec_cmd icv | hercules]
[-drc_runset filename]
[-fill_runset filename]
[-mapfile filename]
[-dp_hosts {list_of_dp_hosts}]
[-num_cpus integer]
```

Data Types

<i>filename</i>	string
<i>list_of_dp_hosts</i>	list

ARGUMENTS

```
-default
    Restores all options to default.

-exec_cmd icv | hercules
    Specifies the name of executable. icv is for IC Validator; hercules is for Hercules. Default is none. The tool searches the executable from standard search path.

-drc_runset filename
    Specifies the foundry runset for design rule checking (DRC). The default is none.

-fill_runset filename
    Specifies the foundry runset for metal filling. The default is none.

-mapfile filename
    Specifies the layer mapping file. This file maps Milkyway layers to runset (GDSII) stream layers. Both Milkyway-formatted or application tool-formatted mapping files (such as a Hercules-formatted mapping file) are acceptable. The default is none.
    The layer mapping file for Hercules format is MWLayer[/MWDataType] > GDSLayer[/GDSDataType]. For example, "10/20 > 22/1" maps MW layer 10 and datatype 20 to GDS layer 22 and datatype 1.

-dp_hosts {list_of_dp_hosts}
    Specifies machines to be used for distributed processing. The default is none. If you do not specify this option, it means that only the local machine CPU is used for the command.
    For example:
```

```

{machine_1 machine_2 machine_3 machine_4}: Uses one cpu from each machine.

{machine_1 machine_1 machine_2 machine_2 machine_3 machine_4}: Uses two cpus
from machine_1 and machine_2 and one cpu from machine_3 and
machine_4.

-num_cpus integer
    Specifies the number of CPUs for distributed processing. The number of CPUs
    should be greater than or equal to 1. The default value is 1.

```

DESCRIPTION

This command sets environment settings for ICV or Hercules before executing the **signoff_drc** or **signoff_metal_fill** command, and so on.

The **report_physical_signoff_options** command reports option values set by the **set_physical_signoff_options** command.

All options are optional.

Note

For the **-num_cpus** and **-dp_hosts** options, the number of CPUs should be less than or equal to the number in the value of the **dp_hosts** option.

Warning

ICV or Hercules runs hierarchically and reports errors in the top level by expanding the lower-level errors without merging them for the purpose of the IC Compiler error browser.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example distributes jobs on 4 cpus among the machines specified by the **-dp_hosts** option for running DRC with a foundry runset called *test.rs*.

```

prompt> set_physical_signoff_options \
-exec_cmd icv \
-dp_hosts {machine_1 machine_2 machine_3 machine_4} \
-num_cpus 4 \
-drc_runset test.rs

```

The following example maps layer 41 and datatype 0 to layer 61 and datatype 0 in the Milkyway-formatted layer mapping file where A is for text and data, 41 is the Milkyway layer number, and 61 is the corresponding layer number defined in the

foundry runset.

A 41 61

The following example shows to map layer 31 and all datatypes to layer 61 and all datatypes in the Hercules formatted layer mapping file, where 31 is the Milkyway layer number and 61 is the corresponding layer number defined in the foundry runset.

31 > 61

signoff_metal_fill(2)

set_physopt_cpulimit_options

Specifies the options for performing a CPU-limited optimization.

SYNTAX

```
status set_physopt_cpulimit_options
[-name limit_name]
[-mode max_delay | design_rule | max_area | tns | max_static_power]
[-absolute_time absolute_time_value]
[-absolute_cost absolute_cost_value]
[-delta_time delta_time_value]
[-delta_cost delta_cost_value]
[-path_group path_group_name]
[-remove]
```

Data Types

<i>limit_name</i>	string
<i>absolute_time_value</i>	int
<i>absolute_cost_value</i>	float
<i>delta_time_value</i>	int
<i>delta_cost_value</i>	float
<i>path_group_name</i>	string

ARGUMENTS

-name *limit_name*

Specifies the name of limit constraint. The string value *limit_name* will be used to refer to this limit constraint and this name can be used for removing an earlier set limit constraint. **-name** is a required option.

-mode max_delay | design_rule | max_area | tns | max_static_power

Specifies the optimization mode for which the runtime limit is to be applied, wherever appropriate . The argument values represent worst setup, design rule, area recovery, TNS, static power recovery optimization respectively.

-absolute_time *absolute_time_value*

Specifies the cputime limit constraint for optimization in physopt. *absolute_time_value* is in minutes and is an integer value. If runtime for the optimization mode for which **-absolute_time** is specified, exceeds *absolute_time_value*, physopt bails out optimization for that mode. This lets you specify different timelimits for different optimization modes. Multiple **-absolute_time** constraints can be set for the session. But only one mode can be constrained per each **set_physopt_cpulimit_options** command. CPU time during optimization can be displayed by adding %cpu keyword to **compile_log_format** variable. **-mode** is optional with **-absolute_time**. If **-mode** is not specified the *absolute_time_value* limit is applied as a sum-total runtime bound for all modes during optimization. **-absolute_time** is exclusive with **-absolute_cost**, **-delta_time**, **-remove**. Other options that **-absolute_time** can be used with is **-mode** along with the required option **-name**.

-absolute_cost absolute_cost_value
 Specifies an absolute cost limit for an optimization mode. If the *absolute_cost_value* absolute cost criteria is met for that optimization mode , that optimization mode is bailed out, and optimization will continue for other modes. **-absolute_cost** takes a float value. **-absolute_cost** is exclusive with **-absolute_time**, **-delta_time**, **-remove**. Other options that **-absolute_cost** can be used with is **-mode** and **-path_group** along with the required option **-name**. For now, **-absolute_cost** bound will only be supported for *max_delay* since *absolute_cost_value* can be abstract for other modes. **-mode** with *max_delay* has to be specified with **-absolute_cost**. If *path_group_name* is also specified, the cost criteria is checked only for the path group in the design named as *path_group_name*. If no *path_group_name* is specified , the cost criteria is applied to the sum total of the worst negative slacks for all path groups in the design. Above summed worst cost can be displayed by adding **%max_delay** keyword to **compile_log_format** variable.

-delta_time delta_time_value
 Specifies a time limit in minutes such that if there is less than the specified *delta_cost_value* cost improvement for that optimization mode, within every block-interval of *delta_time_value* specified timelimit, that optimization mode is terminated . This lets user specify a bailout limit based on the rate at which the cost is getting fixed. **-delta_time** and **-delta_cost** have to specified together. **-delta_time** is exclusive with **-absolute_time**, **-absolute_cost**, **-remove**. Other options that **-delta_time** can be used with is **-mode** along with the required option **-name**. For now, *max_delay* mode option is only supported with **-delta_time**. **-mode** with *max_delay* has to be specified with **-delta_time**. For *max_delay* mode the *delta_cost_value* improvement is calculated as sum total improvement of worst slack over all path groups in the design. Progress of the above summed worst cost can be displayed by adding **%max_delay** keyword to **compile_log_format** variable.

-path_group path_group_name
 Specifies a path group in the design. Takes a string value.

-remove
 This can be used to remove an earlier set **set_physopt_cpulimit_options** limit. The name of the limit has to specified to remove the limit.

DESCRIPTION

This command allows users to specify limits which are 1. runtime based or 2. cost based or 3. based on the rate at which the cost is getting fixed for various optimization modes and run physopt with these limits. Physopt optimization will bailout that optimization mode if any of the appropriate limit constraint is met. **set_physopt_cpulimit_options** lets you specify runtime bounds for optimization alone, independant of other steps (placement, loading etc.) during physopt. The limit options are not saved in the database and applies only for the current session. Limit options are applied afresh for each physopt Stage , and any prior bailouts and all time counters are reset at start of each physopt Stage.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets various **set_physopt_cpulimit_options** limits to physopt.

```
prompt> set_physopt_cpulimit_options -absolute_time 60 \
-name cpulim1
prompt> set_physopt_cpulimit_options -absolute_time 10 \
-mode max_delay -name cpulim2
prompt> set_physopt_cpulimit_options -absolute_time 10 \
-mode design_rule -name cpulim3
prompt> set_physopt_cpulimit_options -absolute_time 10 \
-mode max_area -name cpulim4
prompt> set_physopt_cpulimit_options -absolute_cost 1300 \
-mode max_delay -name cpulim6
prompt> set_physopt_cpulimit_options -absolute_cost 500 \
-mode max_delay -path_group clock -name cpulim8
prompt> set_physopt_cpulimit_options -delta_time 5 \
-delta_cost 50 -mode max_delay -name cpulim9
prompt> physopt -area_recovery
```

The above sequence sets the following limits to physopt, such that if any of the below limits is reached that appropriate optimization mode is terminated, and optimization continues with other modes. On a bailout, information message is printed with keyword (**CPULIMIT**), and the message includes the cpulimit constraint name that caused the bailout. Note that all bailouts and time counters are reset at start of each physopt Stage . 1. Maximum runtime of 60 minutes for entire optimization (summed over all modes) (cpulim1)

2. Maximum runtime of 10 minutes for max_delay setup time optimization. This limit does not affect other modes. (cpulim2)
3. Maximum runtime of 10 minutes for DRC optimization. This limit does not affect other modes. (cpulim3)
4. Maximum runtime of 10 minutes for area recovery. This limit does not affect other modes. (cpulim4)
5. If sum total of worst slack over all path groups betters 1300, max_delay optimization is terminated. (cpulim6)
6. If worst slack of path group clock 500, max_delay optimization of path group clock is terminated. Optimization will continue for other path groups , other modes. (cpulim8)
7. If the sum total worst negative slack over all path groups in the design does not improve by 50 for every 5 minutes, max_delay WNS optimization will be terminated. (cpulim9)

SEE ALSO

compile_log_format(3)

set_pin_name_synonym

Defines synonyms for pin names.

SYNTAX

```
Boolean set_pin_name_synonym
[-full_name]
[-force]
pin_name_synonym
pin_name
```

Data Types

<i>pin_name_synonym</i>	string
<i>pin_name</i>	string

ARGUMENTS

-full_name	Indicates that a pin name synonym is a full name synonym.
-force	Overwrites the existing pin name synonym if a conflict occurs.
<i>pin_name_synonym</i>	Specifies a pin name synonym string for <i>pin_name</i> . This argument is required.
<i>pin_name</i>	Specifies a pin name string for which the synonym is defined. This argument is required.

DESCRIPTION

This command defines pin name synonyms, which are supported in pin object queries.

The *pin_name_synonym* is an alternative pin name for a pin object. For example, if *U1/U2/data_in* is defined as the synonym for the *U1/U2/D* pin, pin query commands can find the pin object named *U1/U2/D* when the commands could not find the pin with the given name *U1/U2/data_in*.

Pin name synonyms are only applicable to pins on leaf-level sequential cells.

Two types of pin name synonyms are supported: full name synonyms and simple name synonyms. The **set_pin_name_synonym** command defines simple name synonyms unless the **-full_name** option is used. When defining a full name synonym, you specify the full hierarchical name for the pin object in both the *pin_name_synonym* and *pin_name* fields. Pin query commands use full name synonyms exactly as they are defined. Simple name synonym definitions use short names for pin objects. Pin query commands use a simple pin name synonym to construct a full pin name during a synonym-based pin object search. You can get full name and simple name synonyms for pin objects by querying **full_name** and **name** attributes for pin objects.

Wildcards and regular expressions are not supported in pin name synonym definitions. Simple name synonyms do not support the forward slash (/) since it is considered a hierarchical separator.

When using the pin name synonyms for pin queries, the full name synonym, when applicable, supersedes the simple name synonym.

EXAMPLES

The following examples use **set_pin_name_synonym** to define pin name synonyms, and show how **get_pins** command uses the synonyms:

```
prompt> set_pin_name_synonym SYN_CD CD
1

prompt> set_pin_name_synonym -full_name \
    this/is/a/synonym mid1/FJK2SP_at_mid/TI
1

prompt> set_pin_name_synonym -full_name \
    mid1/FJK2SP_at_mid/J mid2/bot2/LSR0P_at_bot/Q
1

prompt> set synonym_pin_query_verbose true
true

prompt> get_pins mid1/FJK2SP_at_mid/SYN_CD
Information: found 1 pin using simple name synonym definition {SYN_CD CD}.
{mid1/FJK2SP_at_mid/CD}

prompt> get_pins this/is/a/synonym
Information: found 1 pin using full name synonym definition \
    {this/is/a/synonym mid1/FJK2SP_at_mid/TI} .
{mid1/FJK2SP_at_mid/TI}
```

SEE ALSO

set_pin_physical_constraints

Sets physical constraints per pin instance.

SYNTAX

```
status set_pin_physical_constraints
[-pin_name pin_name]
[-cell cell_name]
[-layers layers]
[-width pin_width]
[-depth pin_depth]
[-side side_number]
[-offset offset_distance]
[-order order_number]
[-off_edge {center | location | auto}]
[-location point]
[objects]
```

Data Types

<i>pin_name</i>	string
<i>cell_name</i>	string
<i>layers</i>	list
<i>pin_width</i>	float
<i>pin_depth</i>	float
<i>side_number</i>	integer
<i>offset_distance</i>	float
<i>order_number</i>	integer
<i>objects</i>	list

ARGUMENTS

[-pin_name *pin_name*]

The pin name identifies the pin for which the specified constraint is to be applied. It is valid to enter pin names even if such a pin does not exist in the design. The constraint is stored in the database even though it might not get applied. In such cases, the constraint is automatically applied when a new pin with this name is added to the design.

This option and the *objects* argument are mutually exclusive. You must specify the pins by using one of these arguments.

[-cell *cell_name*]

Specifies the name of the Milkyway cell or plan group to which the pin belongs. If you specify this option, you must also apply the **-pin_name** option. This option and the *objects* argument are mutually exclusive. You must specify only one.

[-layers *layers*]

Specifies a set of metal layers allowed for the ports or terminals. The argument is a collection of consecutive metal layers. A collection that contains nonconsecutive metal layers is not supported.

[-width *pin_width*]
 Specifies the desired pin width in microns. The default is 0. If the width constraint specified is smaller than the minimum width given in the library, the minimum width is applied (unless otherwise noted).

[-depth *pin_depth*]
 Specifies the desired pin depth in microns. The default is 0. If the depth constraint specified is smaller than the minimum depth given in the library, the minimum depth is applied (unless otherwise noted).

[-side *side_number*]
 Specifies the block side on which the pin must be placed so that it abuts to the specified die edge.
 The side number is a positive integer that starts from 1. Given any shape (rectangular or rectilinear), the lower left-most edge is the starting edge (side number 1). The side number of the next edge, going clockwise, is 2, and so on. You can specify a value of 0 to indicate no side constraint.

[-offset *offset_distance*]
 Specifies the distance in microns that the pins must be offset from the die edge on which they are placed. The offset is the distance to the edge of the pin. The specified value must be a positive floating point number.

[-order *order_number*]
 Specifies the placement order for the relative positions of pins. The order number must be a positive integer. A value of 0 means the pin has no order constraint. If the edge is horizontal, the smaller the number you specify, the more to the left the pin should be placed. If the edge is vertical, the smaller the number you specify, the lower the pin should be placed. In addition, order constrained pins are allowed to be interleaved by other pins. The default is 0.

-off_edge {center | location | auto}
 Specifies what type of off-edge pin it is. The default behavior of this command is to set an on-edge pin constraints.
 The following is a description of the supported values. These values are mutually exclusive. Use only one value.
center
 When **-off_edge center** is specified, the pin is placed in the center of the cell.

location
 When **-off_edge location** is specified, you must provide the location for this pin by using the **-location point** option.
 The pin is placed at the exact coordinates of provided location. In addition, the pin is marked as fixed once it is created.

auto
 When **-off_edge auto** is specified, you must create a pin guide that is associated with this pin and it must be in the center of the block boundary. The pin is placed at the optimal position guided by the pin guide. If you do not provide a pin guide, the pins are placed in the center of the cell, which is the same as **-off_edge center**.

[-location point]
Specifies the coordinates of the off-edge pin. When this option is used, you must also apply the **-off_edge location** option. This option and the **-offset fp option are mutually exclusive. Use only one.**

[objects]
Specifies the pin on which the specified constraints apply. Multiple objects are supported. However, only one object is allowed if the **-order** option is specified.
You can specify either the **-pin_name** or **objects** option to set the pin constraints. However, these options are mutually exclusive. Use only one.

DESCRIPTION

Sets the physical constraints on pins such as layers and width. The constraints you specify are saved when the design is saved.

If you want the constraints to be honored during pin placement, use the **set_fp_pin_constraints -use_physical_constraints** option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to specify physical constraints on a pin.

```
prompt> set_pin_physical_constraints -pin_name "mypin"  
-layers {M2 M3 M4 M5}  
-width 0.28 -depth 0.28 -side 1 -offset 5
```

SEE ALSO

```
read_io_constraints(2)  
report_io_constraints(2)  
remove_io_constraints(2)  
set_pad_physical_constraints(2)  
set_chiplevel_pad_physical_constraints(2)  
set_fp_pin_constraints(2)  
write_io_constraints(2)
```

set_place_opt_cts_strategy

Specifies clock-tree-related options for the **place_opt -cts** command.

SYNTAX

```
status set_place_opt_cts_strategy
[-operating_condition min | max(default) | min_max]
[-no_clock_route]
[-inter_clock_balance]
[-fix_hold]
[-update_clock_latency]
```

ARGUMENTS

```
-operating_condition [min | max(default) | min_max]
Specify operating condition, default is max.

-no_clock_route
Don't perform routing of clock nets.

-inter_clock_balance
Execute inter-clock delay balancing.

-fix_hold
Executes hold time violation fixing during incremental optimization. This
option is off by default.

-update_clock_latency
Updates the latencies on real and virtual clock objects after clock tree
synthesis, clock tree optimization, inter-clock balance (if chosen) and clock
tree detailed routing. This will effectively execute a set_clock_latency
under-the-hood for the clock objects and use the insertion delay of the clock
tree as the latency number. If set_latency_adjustment_options command is
executed before place_opt -cts, then the directives will be obeyed. If no
directives are given, then only the latencies of real clock objects will be
updated. The update mechanism uses the insertion delay of the clock tree as
the latency number.
```

DESCRIPTION

The **set_place_opt_cts_strategy** command defines clock tree related options that will later be used by a subsequently issued **place_opt -cts** command in the same session. Note that these options are applicable only for **place_opt -cts** command. If **-cts** option is not used for running **place_opt**, then all of the values specified during this command are ignored during that invocation of place_opt.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command sets up operating condition as min for a subsequently issued **place_opt -cts** command. It also sets up **place_opt -cts** to execute inter-clock delay balancing.

```
prompt> set_place_opt_cts_strategy -operating_condition min -inter_clock_balance
```

SEE ALSO

place_opt(2)
clock_opt(2)

set_pnet_options

Sets up placement tools to avoid power strap violations.

SYNTAX

```
int set_pnet_options
[-partial | -complete | -none]
[-min_height height_threshold]
[-min_width width_threshold]
[-no_via_additive]
[-density value]
[-see_object object_type_names]
layer_names
```

Data Types

<i>height_threshold</i>	float
<i>width_threshold</i>	float
<i>value</i>	float
<i>object_type_names</i>	list
<i>layer_names</i>	list

ARGUMENTS

-partial

Allows standard cells to be placed under pnets, but the pins in the standard cells are checked to prevent shorts with the pnets. The **-partial**, **-complete**, and **-none** options control how the tool places the cell under the pnets. These three options are mutually exclusive; you can specify only one. If you do not specify this option, **-none** is used as the default.

-complete

Prevents cells from ever overlapping with pnets. A pnet is treated as a placement keepout. The **-partial**, **-complete**, and **-none** options control how the tool places the cell under the pnets. These three options are mutually exclusive; you can specify only one. If you do not specify this option, **-none** is used as the default.

-none

Allows cells to be freely placed under pnets without checking for electrical shorts. The pnets are invisible during placement. The **-partial**, **-complete**, and **-none** options control how the tool places the cell under the pnets. These three options are mutually exclusive; you can specify only one. If you do not specify this option, **-none** is used as the default.

-min_height *height_threshold*

Specifies the wide metal threshold height value. If a pnet width or pnet height is less than the specified threshold, the tool automatically treats the pnet as partial blockage. You can use this option only if you also specify the **-partial** or **-complete** option. If a pnet width or pnet height is equal to or more than the specified threshold, the pnet is treated as a complete blockage regardless of whether you specify the **-partial** or **-complete** option.

This option is not applied to power rails. Power rails are always treated as partial blockages.

See the DESCRIPTION section for the definition of power rails. By default, when this option is used with the **-complete** option, the default threshold height is 0. When it is used with the **-partial** option, the default threshold is layer dependent. For metal 1 (M1) and metal 2 (M2), the default height threshold is $(\text{core_site_height})/2$. For metal 3 (M3) and above, the threshold height is 10000 microns.

`-min_width width_threshold`

Specifies the wide metal threshold width value. If a pnet width or pnet height is less than the specified threshold, the tool automatically treats the pnet as partial blockage. You can use this option only if you also specify the **-partial** or **-complete** option. If a pnet width or pnet height is equal to or more than the specified threshold, the pnet is treated as a complete blockage regardless of whether you specify the **-partial** or **-complete** option. This option is not applied to power rails. Power rails are always treated as partial blockages.

`-no_via_additive`

Turns off via additive checking. Via additive is the difference in width and height between the lower level metal and the higher level metal inside the via. For example, given that VIA12 contains M1 and M2, the size difference between M2 and M1 is the via additive. This option assumes the via additive is 0. (The tool assumes the via can be dropped along the edge of the M1 pin and just checks the M2-M2 spacing rule from the pin to pnet strap). You can use this option only when the physical library includes the via geometry inside the port geometry definition.

`-density value`

Specifies the density of cells under the power nets on a certain layer. The value must be between **0** and **1**. If the specified value is **1**, the entire area under the pnet is available for cell placement. If the specified value is **0**, the area under the pnet is not available for cell placement. If the specified value is **0.3**, 30% of the area under the pnet can be covered with placed cells. This option cannot be used with the **-complete** option.

`-see_object object_type_names`

Specifies the route object types to be considered by the legality checker during the **physopt**, **legalize_placement**, and **check_legality** commands. These settings are general to all layers specified for the command. The valid values for this option are the following: **all_types**, **none**, **pg_ring**, **pg_strap**, **pg_pin_conn**, **clk_ring**, **clk_strap**, **bus**, **path**, **user_signal**, **rect**, and **contact_array**. By default, the PG ring, PG strap, PG pin connection, clock ring, clock strap, and path types are enabled; and the bus, user signal, rectangle, and contact array types are disabled.

`layer_names`

Specifies the pnet layer names, such as {Metal1 Metal2}. You can get the layer names from the report generated by using the **report_lib -physical** command or directly from the physical library file.

DESCRIPTION

This command verifies that there are no metal-to-metal violations between cells and power net segments by configuring the placement tools (**create_placement**, **legalize_placement**, **check_physical_constraints**, **physopt**, and **check_legality**).

This command sets attributes for each routing layer, which are stored in the design database. To determine the current values, use the **report_pnet_options** command. To remove the attributes so that you can re-apply a new set of values, use the **remove_pnet_options** command. Using **set_pnet_options** overwrites all previous settings for that layer. To retain some of the previous settings, define them again. You can specify for each layer to be either a complete blockage or a partial blockage. You can do this by using the **-none** option to specify whether routing layers are to be ignored during legality checking (). Irrespective of the options specified in this command, the pnets on the routing layers are still used for routing congestion purposes.

When you use the **-partial** option, if there is no standard cell pin on the the routing layer or the layer just below the routing layer, then this pnet layer is ignored because the standard cells can be freely placed under the pnets on the layer. For example, if you specify **-partial {M5}** but there is no M5 or M4 pin in any standard cell, then all the M5 pnets are ignored.

When you use the **-partial** or **-complete** option, power rails are always treated as partial blockages (although the pnet layer is set as a complete blockage, and the threshold is set smaller than the power rails width). A power rail is metal across the row top and bottom line, and the width is smaller than (core site height/2). To adjust the power rail height threshold, set the **physopt_power_rail_height_limit** variable. For example, if you set this variable to **1.2**, the tool recognizes the pnets that cross the site rows and have a height of less than 1.2 microns as power rails.

To apply pnet options for different layers, annotate the floorplan data to the design before using the **set_pnet_options** command. When you again annotate the floorplan data on the design, it resets the pnet options set on the design. After this, you must again use the **set_pnet_options** command to set the pnet options.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the *metal1* to *metal4* layers as partial blockages. The default minimum width for *metal1* and *metal2* is the average cell width of *10.0*. The default minimum height for *metal1* and *metal2* is the core site height (*12.0*) divided by *2* = *6.0*. The default minimum width and height for *metal3* and *metal4* is *10000* microns.

```

set_port_fanout_number

Sets the number of external fanout points driven by specified ports in the current design.

SYNTAX

```
status set_port_fanout_number
fanout_number
port_list
```

Data Types

<i>fanout_number</i>	float
<i>port_list</i>	list

ARGUMENTS

fanout_number

Specifies the number of external fanout points driven by the ports in *port_list*. Use this command only with ports. An error message occurs if *port_list* contains any nets. The input value is interpreted as an integer, non-integer values are truncated, and the integer portion is used as the fanout number.

port_list

Specifies a list of ports in the current design whose fanout numbers are to be set.

-max

-min

DESCRIPTION

This command sets the **fanout** attribute on specified ports in the current design. The fanout attribute sets the number of external fanout points driven by each port. This information is used to calculate an external wire load value for the corresponding port. The external wire load value is then added to the wire load of the net connected to the port. Setting this value to 0 when the driver of the port has no other internal fanout causes the net driving the port to be treated as unconnected, so it may be skipped for DRC.

Use the **report_port** command to view the load values on ports.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following sequence of commands describes the external fanout of an output port:

```
prompt> set_port_fanout_number 5 [get_ports 01]  
prompt> set_wire_load_model [get_ports 01] \  
"default_wl"
```

set_drive(2)
set_load(2)
target_library(3)

set_port_location

Annotates the specified top-level port with x- and y-coordinates and layer geometry, which the tool uses when running the **reoptimize_design** command.

SYNTAX

```
status set_port_location
[-coordinate {x y}]
[-layer_name layer_name]
[-layer_area {lx ly ux uy}]
[-append]
port_name
```

Data Types

<i>x</i>	float
<i>y</i>	float
<i>layer_name</i>	string
<i>lx</i>	float
<i>ly</i>	float
<i>ux</i>	float
<i>uy</i>	float
<i>port_name</i>	string

ARGUMENTS

-coordinate {*x y*}
Specifies the absolute location, in microns, of the x- and y-coordinates of the port.

-layer_name *layer_name*
Specifies the layer name of the top-level design port whose layer geometry is to be annotated.

-layer_area {*lx ly ux uy*}
Specifies the layer geometry of the port, in microns.

-append
Appends the location of port shapes to the same port. If this option is omitted, the location provided by the command overwrites the existing location.

port_name
Specifies the name of the top-level design port whose location is to be annotated.

DESCRIPTION

This command annotates the port location on the specified port. Executing this command without coordinates resets the port location. You can also set the port layer geometry by specifying layer name and layer area coordinates.

The location of the port specified with this command takes precedence over any annotation from a PDEF file using the **read_pdef** or **read_clusters** command. However, if the port location is reset by executing the **set_port_location** command without the x- or y-coordinates, any annotation from the PDEF file is used during optimization.

Layer area geometry is relative to the port origin.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example annotates port Z, a top-level port in the current design, with the location at 100, 5000.

```
prompt> set_port_location -coord {100 5000} Z
```

The following example resets the location of port Z. The tool uses physical information from any PDEF file to determine the location of port Z.

```
prompt> set_port_location Z
```

The following example sets the layer geometry of rectangle 10*20 of port Z.

```
prompt> set_port_location -layer_name METAL1 \  
-layer_area {-5 -10 5 10} Z
```

SEE ALSO

set_power_gating_signal

Sets the attributes on the ports or pins in the design to indicate the power gating pins and the type of retention registers that will use the ports or pins to connect to or through the corresponding design hierarchy.

SYNTAX

```
integer set_power_gating_signal
[-power_pin_index index]
[-library_pin library_pin_name]
[-type style]
ports_or_pins
```

Data Types

<i>index</i>	integer
<i>library_pin_name</i>	string
<i>style</i>	string
<i>ports_or_pins</i>	list

ARGUMENTS

-power_pin_index *index*

Specifies the value of the **power_pin_class** attribute.

-library_pin *library_pin_name*

Specifies the pin name of of retention registers in the library to get the **power_pin_class** attribute.

-type *style*

Specifies the **power_gating_style** attributes.

ports_or_pins

Specifies a list of ports or pins to which the attributes are applied.

DESCRIPTION

Power Compiler can hook up the control pins of retention registers through the design hierarchy to some primary input ports of the design or to some output pins of driving cells in the design.

There are two steps to perform the stitching process. First, specify the ports or pins on the design hierarchy you want to use to be connected to a certain kind of control pins of a certain style of retention registers. Second, stitch the control pins across the design hierarchy.

The **set_power_gating_signal** command is used for the first step. There are 2 attributes to identify to the ports or pins on each design hierarchy what kind of control pins of what type of retention registers to be connected to. One is the **power_pin_class** attribute. It specifies the index of the control pin of a retention register. The index is defined in the target library with the **power_gating_pin**

complex attribute. As many as 5 control pins are supported for the retention registers. The first value of the complex can be `power_pin_[1-5]`. This corresponds to the 1 - 5 of the **power_pin_class** attribute. The other is **power_gating_style**. It specifies the type of retention registers involved.

The **power_pin_class** attribute is specified by the **-power_pin_index** option. You can also use the **-library_pin** option as an alternative. The **-library_pin** option can use the names of control pin of retention registers in the target library to get the value of **power_pin_class** to be used for the command. The pin name is easier to use but it requires that the corresponding control pins of retention registers in the target library have the same **power_gating_pin** attribute.

The **power_gating_style** attribute is specified by the **-type** option. It is the same as the value of the **power_gating_cell** attribute of some retention registers in the target library. If this option is not set, the port or pin will only be used for stitching the control pin of all types of retention registers.

The command can work on both ports of the current design, hierarchical input pin and output pin of a cell. If the command is used on the output pin of a cell, the stitching process will stop at this pin, otherwise it will go through the hierarchical pins to the primary input port of current design.

EXAMPLES

The following example sets the power gating style to *FOO* and the power pin class to 1 on all pins with the name *my_pin* of U1:

```
prompt>set_power_gating_signal -type FOO -power_pin_class 1 [get_pin U1/my_pin
```

The following example sets the **power_pin_class** attribute to a value from the **power_gating_pin** attribute of pin *my_pin* in the target_library.

```
prompt>set_power_gating_signal -library_pin my_pin [get_pin U1/pin1
```

SEE ALSO

`hookup_power_gating_ports(2)`
`report_power_gating(2)`
`set_power_gating_style(2)`
`attributes(3)`
`power_enable_power_gating(3)`
`target_library(3)`

set_power_gating_style

Sets the **power_gating_style** attributes on designs, cell instances, or HDL blocks, to specify the type of retention register cells from the target library used by the **compile** command.

SYNTAX

```
int set_power_gating_style
-type style
[-hdl_blocks hdl_blocks]
[-hierarchy]
[cell_or_design_list]
```

Data Types

<i>style</i>	string
<i>hdl_blocks</i>	string
<i>cell_or_design_list</i>	list

ARGUMENTS

-type *style*
Specifies the power gating style of retention flip-flops in the target library that will be used by the **compile** command. The power gating style is defined by the **power_gating_cell** cell level attribute in the target library.

-hdl_blocks *hdl_blocks*
Specifies the names of HDL blocks in which to use the retention registers with the specified power gating style.

-hierarchy
Searches through the design hierarchy to find the HDL blocks and sets the power gating style. By default, power gating styles are set only on the HDL blocks in the current design. This option is intended for use with the **-hdl_blocks** option.
If you specify cells in the **set_power_gating_style** command, this option is not necessary, because the command searches through the design hierarchy for cells by default.

cell_or_design_list
Specifies a list of leaf-level cells or designs in which to use the retention registers with the specified power gating style. The default is to use the current design.

DESCRIPTION

This command specifies the power gating style on designs, cells, or HDL blocks to indicate the specific type of retention registers from the target library to use to map the sequential cells in the **compile** command. The retention registers in the libraries have a **power_gating_cell** cell level attribute to specify the power gating styles of the registers.

If two **set_power_gating_style** commands specify the cells or HDL blocks containing the same cell, the last command overrides the previous command. The power gating style set on a design is the default style used on all sequential elements in the design. It has lower priority than the power gating style on HDL blocks and cells.

HDL block gating accepts wildcards, but the wildcards are only effective in one hierarchy.

This command requires a Power Compiler license and is only effective when the **power_enable_power_gating** variable is set to **TRUE**.

EXAMPLES

The following example specifies that the retention registers with the *FOO* style in the target libraries for the current design are to be used to map sequential cells:

```
prompt> set_power_gating_style -type FOO
```

The following example indicates that the retention registers with the *FOO* style in the target libraries for all HDL blocks whose name starts with *HDL_BLOCK*:

```
prompt> set_power_gating_style -type FOO \
-hdl_blocks HDL_BLOCK*
```

The following example sets the *U1* and *U3* cells to the *FOO* style, and sets the *U2*, *U4*, and *U6* cells to the *BAR* style:

```
prompt> set_power_gating_style -type FOO {U1 U2 U3}
prompt> set_power_gating_style -type BAR {U2 U4 U6}
```

The following example specifies that the *H1* design HDL block and the *U1*, *U2*, and *U3* cells have the *FOO* power gating style:

```
prompt> set_power_gating_style -type FOO \
-hdl_blocks H1 {U1 U2 U3}
```

In the following example, assume the *U1*, *U2*, and *U* cells are in the *H1* HDL block. The following command specifies that the *U1*, *U2* and *U3* cells have the *BAR* power gating style, and other cells in *H1* have the *FOO* power gating style:

```
prompt> set_power_gating_style -type FOO -hdl_blocks H1
prompt> set_power_gating_style -type BAR {U1 U2 U3}
```

set_power_gating_style

2562

set_power_guide

Sets an existing exclusive movebound as power guide or power well. This power guide will be used as always-on power_guide.

SYNTAX

```
status set_power_guidefp
-name exclusive_movebound_name
[-guard_band_x horizontal_guard_band_width]
[-guard_band_y vertical_guard_band_width]
```

Data Types

<i>exclusive_movebound_name</i>	string
<i>horizontal_guard_band_width</i>	integer
<i>vertical_guard_band_width</i>	integer

ARGUMENTS

-name *exclusive_movebound_name*
Indicates the name of an existing exclusive movebound which needs to be set as power guide or power well.

-guard_band_x *horizontal_guard_band_width*
Facilitates obtaining an integral width for the guard band in the horizontal direction.

-guard_band_y *vertical_guard_band_width*
Facilitates obtaining an integral width for the guard band in the vertical direction.

DESCRIPTION

This command sets an existing exclusive movebound as power guide. Currently this command is only used for making an exclusive movebound as always on power guide or power well.

The always on power guides in shut down voltage areas are used for placing the regular cells on the always on paths so that those cells become always on.

If there is no voltage area exist in the design, no exclusive movebound can be set as power guide. In a design with voltage area, if an exclusive movebound is contained in default voltage area and is set as power guide, addition or removal of a voltage area might results into incorrect inclusion or exclusion of power guides. It is recommended to set power guide only after the design is fixed with respect to voltage areas in it.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows a flow of the **set_power_guide** command. In this flow, AO_WELL physically belongs to voltage area VA_SHUTDN, and AO_WELL is set as an always_on power guide.

```
prompt> create_bounds -name AO_WELL\  
-coordinate {10 10 20 20} -exclusive  
prompt> create_voltage_area -name VA_SHUTDN\  
-coordinate {5 5 30 30} [get_cells A_INST]  
prompt> set_power_guide -name AO_WELL
```

SEE ALSO

`create_bounds(2)`
`create_voltage_area(2)`
`report_power_guide(2)`
`unset_power_guide(2)`

set_power_net_to_voltage_area

Links, unlinks, or reports power nets for the specified voltage area.

SYNTAX

```
status set_power_net_to_voltage_area
[-action link | unlink | report]
[-voltage_area voltage_area_name voltage_area_name]
[-power_net net_name]
```

Data Types

<i>net_name</i>	string
-----------------	--------

ARGUMENTS

-action link | unlink | report

Specify the action of the power net to the specified voltage area. In the "link" action, the p/g net name is linked to the voltage area. In the "unlink" pattern, the p/g net name is unlinked to the voltage area. In the "report" action, the p/g nets currently associated with the voltage area are printed.

-voltage_area *voltage_area_name* *voltage_area_name*

Specify the name of the voltage area.

-power_net *net_name*

Specify the net name to be linked/unlinked to/from the voltage area.

DESCRIPTION

This command link, unlink, or report p/g net name to the specified voltage area for multi-vdd support.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> set_power_net_to_voltage_area -action link
                  -voltage_area test -power_net VDD
```

set_power_options

Specifies options for power optimization.

SYNTAX

```
status set_power_options
[-default]
[-leakage true | false]
[-dynamic true | false]
[-low_power_placement true | false]
[-clock_gating true | false]
[-leakage_effort low | high]
[-dynamic_effort low | high]
```

ARGUMENTS

-default

Specifies default option for Power Optimization. By default only leakage optimization is set to true. All the options previously set will be reset with this option.

-leakage true | false

Specifies the option to the tool to run Leakage power optimization. By default the option is true.

-dynamic true | false

Specifies the option to the tool to run dynamic power optimization. Dynamic Power optimization runs only when the option is set to true. By default the option is false.

-low_power_placement true | false

Specifies the option to the tool to run power aware placement. When the option is set to true, the tool estimates high activity nets. This estimation is used to perform switching activity-based power aware placement that shortens the wire lengths of the nets with higher switching activities, while optimizing timing, power and congestion, concurrently. This feature is available in place_opt -power, clock_opt -power, and optimize_pre_cts_power commands. When used in clock_opt -power or optimize_pre_cts_power, the tool performs clock tree estimation to consider high activity clock nets as well as signal nets. In case that area is the biggest concern so a very light place_opt is required, low power placement technology is not recommended in place_opt with -effort low; Even though overall dynamic power can be improved, area could be worse, due to more extra steps for placement and optimization in place_opt. By default the option is false.

-clock_gating true | false

Specifies the option to the tool to perform clock gate restructuring in pre-CTS power optimization. This feature is only available in clock_opt -power and optimize_pre_cts_power commands. By default the option is false.

-leakage_effort low | high

Specifies the option to run low effort or high effort leakage opto. Low effort

leakage opto does cell swapping only. High effort leakage opto produces better leakage power but takes additional runtime. By default leakage optimization runs in high effort.

-dynamic_effort low | high

Specifies the option to run low effort or high effort dynamic power optimization. By default dynamic power optimization is low-effort. High effort dynamic power optimization causes long overhead in runtime.

DESCRIPTION

This command provides the user a flexible interface to control different power optimization techniques inside the tool. These options work in conjunction with mega commands like place_opt, clock_opt and route_opt, when power optimization is enabled by -power switch. It also works with psynopt command. Certain power optimization features are not available in certain mega commands. For example, route_opt supports only leakage power optimization. When the options are specified, the power constraints are optional. However it is recommended to provide power constraints to the tool, so that the tool spend less runtime trying more and more to optimize for power to meet the constraints.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to set power optimization options

```
prompt> set_power_options -leakage true -dynamic true  
  
prompt> place_opt -power  
prompt> set_power_options -low_power_placement true  
prompt> place_opt -power  
prompt> psynopt -power  
prompt> clock_opt -power  
prompt> route_opt -power
```

SEE ALSO

place_opt(2)
clock_opt(2)
route_opt(2)

set_prefer

Sets the **preferred** attribute on specified library cells.

SYNTAX

```
integer set_prefer
[-min]
cell_list
```

Data Types

cell_list list

ARGUMENTS

-min

Specifies the library cells that should be preferred during hold violation (minimum path) fixing.

cell_list

Specifies the list of cells on which to set the **preferred** attribute. Cell names must contain a library prefix. If more than one cell name is specified, enclose the list using quotation marks ("") or braces ({}).

DESCRIPTION

The **set_prefer** command sets the **preferred** attribute on specified library cells. The cells must be in one of the target libraries, or in a library already loaded into Design Analyzer. If this attribute exists on a library cell, the **compile** command uses the library cell attribute before other attributes in the target library that implement the same function during technology translation using the **translate** command.

Note that the effect of the **preferred** attribute might not be noticeable during optimization because non-preferred cells can be chosen to help meet constraints.

If the **-min** option is used, the library cells specified will be preferred during hold violation fixing. Only buffers and inverters, which are used to fix hold violations, should be included in the cell list. Including cells with any other functionality in the list with the **-min** option will have no impact on the optimization engine. This option should be used carefully, because the preferred cells will be used for minimum path fixing, even if it results in a worse area or cell count solution.

The **set_prefer** command affects only the version of the library that is currently loaded into memory, and has no effect on the version that exists on disk. However, if the library is written using **write_lib**, the **preferred** attribute is also written, causing cells to be permanently preferred.

To remove the **preferred** attribute, use the **remove_attribute** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command specifies that the GA and GB cells from the tech_lib library be preferred during optimization.

```
prompt> set_prefer {tech_lib/GA tech_lib/GB}
```

SEE ALSO

[remove_attribute\(2\)](#)
[report_lib\(2\)](#)
[target_library\(3\)](#)

set_preferred_routing_direction

Sets the preferred routing direction for the specified routing layers.

SYNTAX

```
string set_preferred_routing_direction
-layers list_of_layers
-direction horizontal | vertical
```

ARGUMENTS

```
-layers list_of_layers
        Specify the list/collection of layer(s) for which the preferred routing
        directions is to be set.

-direction horizontal | vertical
        Specify the preferred routing direction. The allowed values are: horizontal,
        vertical, h, v, HORIZONTAL, VERTICAL, H, V. Specify any one.
```

DESCRIPTION

The `set_preferred_routing_direction` command is used to set the preferred direction for the specified routing layers. This command will be useful in overriding the default layer directions specified in the library itself or even the design. The setting of layer direction done through this command will become specific to this design only.

Note: The command will issue suitable warnings whenever adjacent layers have the same direction after the execution of the command.

Note: This command overrides the preferred direction specified in the reference libraries and saves the user setting as persistent data (will be written when user saves the design) in the design database.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example assigns layers "m1" & "m2" the direction horizontal.

```
prompt> set_preferred_routing_direction \
    -layers {m1 m2} -direction horizontal
```

SEE ALSO

```
remove_preferred_routing_direction(2)
report_preferred_routing_direction(2)
```

set_preroute_advanced_via_rule

Sets preroute advanced via rule options.

SYNTAX

```
integer set_preroute_advanced_via_rule
[-move_via_to_center]
[-offset_both_sides]
[-x_offset_recommended]
[-y_offset_recommended]
[-x_offset distance]
[-y_offset distance]
[-x_step distance]
[-y_step distance]
[-cut_layer layer]
[-contact_code contact]
[-size_by_via_area {distance distance}]
[-size_by_array_dimensions {int int}]
[-rotation_mode on / required / off]
```

Data Types

distance *distance*

ARGUMENTS

-move_via_to_center

Move advanced via to center of the wire intersection area. When this option is on, all options related to offsets, are irrelevant. Default is not to move via to center.

-offset_both_sides

Applies the X/Y offsets to both lower-left and upper-right corner of the wire intersection area. By default, the offsets are applied only to the lower-left corner of the wire intersection area.

-x_offset_recommended

Select to apply the X offset, specified in *x_offset*, if possible. If this option is skipped, the X offset is forcibly applied.

-y_offset_recommended

Select to apply the Y offset, specified in *y_offset*, if possible. If this option is skipped, the Y offset is forcibly applied.

-x_offset *distance*

Determines the location for the first advanced via by specifying the X offset from the lower-left corner of the wire intersection area. The default is **0.0**.

-y_offset *distance*

Determines the location for the first advanced via by specifying the Y offset from the lower-left corner of the wire intersection area. The default is **0.0**.

-x_step *distance*
 Specifies the distance to put between the advanced vias. The value you type for *distance* is in user units and is the distance between the two left sides of adjacent via arrays in the X direction. When there are design rule checking violations, some vias might not be created. The default is **0.0**.

-y_step *distance*
 Specifies the distance to put between the advanced vias. The value you type for *distance* is in user units and is the distance between the two left sides of adjacent via arrays in the Y direction. When there are design rule checking violations, some vias might not be created. The default is **0.0**.

-cut_layer *layer*
 Specifies via layer name or number from the technology file. This option is mutually exclusive with *contact_code* option. If either option is skipped, the other options of this command are applied to all non-specified via layers by default.

-contact_code *contact*
 Specifies via contact code name or number from the technology file. This option is mutually exclusive with *cut_layer* option. If either option is skipped, the other options of this command are applied to all non-specified via layers by default.

-size_by_via_area {*distance distance*}
 Specifies the X by Y via array area in user units. This option is mutually exclusive with *size_by_array_dimensions* option.

-size_by_array_dimensions {*int_int*}
 Specifies the number of via columns and rows. This option is mutually exclusive with *size_by_via_area* option.

-rotation_mode on | required | off
 Specifies the via rotation mode. It's on by default.

DESCRIPTION

The **set_preroute_advanced_via_rule** command sets the rules of creating via arrays at wire intersections per specified via layer or contact code for some preroute commands. It is sometimes advantageous to create a matrix of small via arrays instead of one large via array at wire intersections. Using smaller via arrays may free some routing space.

It is similar to *special_via_rule* of some preroute commands, except it's advanced in a sense that *special_via_rule* provides the means to specify the same conditions for all layers only, and **set_preroute_advanced_via_rule** allows to specify different conditions for different layers.

In order to create vias in accordance with **set_preroute_advanced_via_rule** settings, user has to turn the "advanced_via_rules" option On in preroute commands that support advanced via rules. Right now only "create_power_straps" and "preroute_standard_cells" commands have the "advanced_via_rules" option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to set **set_preroute_advanced_via_rule** for cut layers V1 through V3, with different array dimension sizes.

```
set_preroute_advanced_via_rule -cut_layer V1 -size_by_array_dimensions {2 1}
set_preroute_advanced_via_rule -cut_layer V2 -size_by_array_dimensions {2 2}
set_preroute_advanced_via_rule -cut_layer V3 -size_by_array_dimensions {1 1}
```

SEE ALSO

[preroute_standard_cells\(2\)](#)

set_preroute_drc_strategy

Sets preroute drc options to change the internal rules for design rule checking in the following power and ground commands: **create_rectangular_rings**, **create_pad_rings**, **create_power_straps**, **create_preroute_vias**, **preroute_instances**, and **preroute_standard_cells**.

SYNTAX

```
status set_preroute_drc_strategy
[-spacing_rules radial | manhattan]
[-protect_pin_access_edge]
[-protect_pin_access_edge_within_pin_layer_pitch]
[-protect_pin_access_edge_within_range protect_range]
[-treat_fat_blockage_as_fat_wire]
[-use_fat_via]
[-ignore_std_cells]
[-ignore_top_level_pins]
[-ignore_same_net_check]
[-quick_check]
[-merge_thin_wires]
[-no_design_rule]
[-report_fail]
[-jog_range jog_range_distance]
[-min_layer min_layer]
[-max_layer max_layer]
[-honor_shapes_of_nets collection_of_nets | ALL]
```

Data Types

<i>protect_range</i>	distance
<i>jog_range_distance</i>	distance
<i>min_layer</i>	string
<i>max_layer</i>	string
<i>collection_of_nets</i>	collection

ARGUMENTS

-spacing_rules radial | manhattan

Specifies the mode for design rule checking (DRC). The valid *rule_mode* values are **radial** or **manhattan**. A **radial** rule checks for spacing violations within a circular area. A **manhattan** rule checks for spacing violations within the defined spacing distance horizontally and vertically. The default value is **radial**.

-protect_pin_access_edge

Prevents the signal pin access edge from being blocked by the Prerouter.

-protect_pin_access_edge_within_pin_layer_pitch

Protects the pin access edge within the double pin layer pitch distance. The default is determined by the following formula:
2 * the MAX pitch in the tech file.

```

-protect_pin_access_edge_within_range protect_range
    Protects the pin access edge within the specified range. The default is
    determined by the following formula:
    2 * the MAX pitch in the tech file

-treat_fat_blockage_as_fat_wire
    Treats fat blockages as fat wires. By default, DRC treats fat blockages as
    thin wires.

-use_fat_via
    Uses fat vias for non-turning layer changes if either wire meets the width
    requirement for a fat via.

-ignore_std_cells
    Turns off DRC against objects in standard cells.

-ignore_top_level_pins
    Ignores top-level pins in DRC. The DRC with such pins is disabled.

-ignore_same_net_check
    Ignores the same net metal-to-metal in DRC.

-quick_check
    Skips the final stage of DRC when a possible same net metal-to-metal error
    is found. On that stage, the DRC engine searches for other metal objects that
    cover the insufficient gap between the two objects; and, if the gap is
    covered, the error is considered to be fake. While using this option might
    decrease runtime, it might cause missing connections.

-merge_thin_wires
    Specifies for the prerouter to check and merge thin wires into fat wires for
    DRC. Using this option might increase runtime.

-no_design_rule
    Turns off all DRC.

-report_fail
    Reports detailed information about the failed power and ground command
    operation.

-jog_range jog_range_distance
    Sets a jogging range distance. Jogging range defines the maximum distance for
    a dogleg connection on the same layer; it is not for layer switching. Set a
    range within which the prerouter might perform limited jogging when
    necessary. The default is 0.0 (as in no jogging).

-min_layer min_layer
    Sets the minimum metal layer used for prerouting. A layerNumber or maskName
    from the technology file is a valid min_layer value. The default value is set
    to the bottom routing layer.

-max_layer max_layer
    Sets the maximum metal layer used for prerouting. A layerNumber or maskName
    from the technology file is a valid max_layer value. The default value is set
    to the top routing layer.

```

```
-honor_shapes_of_nets collection_of_nets | ALL
    Sets the list of nets for which prerouter commands should honor routing. Use
    the collection_of_nets argument to specify a list or the keyword ALL to honor
    the routing of all nets. By default, if a net is not marked as power or ground,
    then the command ignores all of its routing shapes.
```

DESCRIPTION

This command changes the internal rules for design rule checking (DRC) in the following PG commands: **create_rectangular_rings**, **create_pad_rings**, **create_power_straps**, **create_preroute_vias**, **preroute_instances**, and **preroute_standard_cells**

The DRC rules are still taken from Technology File, but this command changes the rule application within the scope of power and ground commands. If the same internal rules are applied for all power and ground commands, the **set_preroute_drc_strategy** command can be executed only once before any of the power and ground commands are executed. These settings are not persistent in the design. This command is optional, if you only want defaults to apply. All the options in this command are optional, as well.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets manhattan rule, prohibits blocking of the pin access edge, directs the prerouter to perform limited jogging in the range of **100** user units, using layers from metal 3 (**M3** in .tf) to metal 5 (**M5** in .tf).

```
prompt> set_preroute_drc_strategy -spacing_rules manhattan \
-predict_pin_access_edge -jog_range 100 \
-min_layer M3 -max_layer M5
```

The following example sets the routing of all nets to honor.

```
prompt> set_preroute_drc_strategy -honor_shapes_of_nets ALL
```

The following example sets the routing of the nets named **timer_hmsb[1]** and **io_if/D1935** to be honored.

```
prompt> set_preroute_drc_strategy -honor_shapes_of_nets \
[get_nets [list timer_hmsb[1] io_if/D1935]]
```

ARGUMENTS

- name name**
Specifies a name for the set of rules. This name is used to reference the rules in subsequent **create_power_straps** and **preroute_instances** commands.
- do_not_connect_pins**
Prevents connections between created routing shapes and pins on other layers.
- extension_layers ext_layers_list**
Sets a list of metal layers on which the tool must create connecting segments. Each layer is specified by its name.
This extension option controls an aspect of the geometry of power strap connections (created by the **create_power_straps** command) or I/O pads (created by the **preroute_instances** command) when it is impossible to make a connection by using only the primary metal layer. For more information on these options, see the *DESCRIPTION* section. To turn the rules on, you must use all of the following options: **-extension_width**, **-extension_space**, **-extension_count**, and **-extension_via_array**.
- extension_width segments_width**
Sets the width of the segments in the connection. The minimum and maximum widths specified in the technology file override this setting. If the specified width is less than the minimum width specified in the technology file, the tool uses the minimum width from the technology file. If the specified width is greater than the maximum width specified in the technology file, the tool uses the maximum width from the technology file.
This extension option controls an aspect of the geometry of power strap connections (created by the **create_power_straps** command) or I/O pads (created by the **preroute_instances** command) when it is impossible to make a connection by using only the primary metal layer. For more information on these options, see the *DESCRIPTION* section. To turn the rules on, you must use all of the following options: **-extension_width**, **-extension_space**, **-extension_count**, and **-extension_via_array**.
- extension_space space_between_segments**
Sets the spacing between connecting segments on the same layer. If the specified spacing is less than the minimum spacing defined in the technology file, the tool uses the minimum spacing from the technology file.
This extension option controls an aspect of the geometry of power strap connections (created by the **create_power_straps** command) or I/O pads (created by the **preroute_instances** command) when it is impossible to make a connection by using only the primary metal layer. For more information on these options,

see the *DESCRIPTION* section. To turn the rules on, you must use all of the following options: **-extension_width**, **-extension_space**, **-extension_count**, and **-extension_via_array**.

-extension_count {min_count max_count}

Sets a range of required parallel connections on one metal layer. If the number of those connections is less than *min_count*, the entire connection is not created. The following condition must be true: $1 \leq \text{min_count} \leq \text{max_count}$.

This extension option controls an aspect of the geometry of power strap connections (created by the **create_power_straps** command) or I/O pads (created by the **preroute_instances** command) when it is impossible to make a connection by using only the primary metal layer. For more information on these options, see the *DESCRIPTION* section. To turn the rules on, you must use all of the following options: **-extension_width**, **-extension_space**, **-extension_count**, and **-extension_via_array**.

-extension_via_array {columns_count rows_count}

Sets the dimensions of the via arrays connecting the segment on the primary metal layer.

This extension option controls an aspect of the geometry of power strap connections (created by the **create_power_straps** command) or I/O pads (created by the **preroute_instances** command) when it is impossible to make a connection by using only the primary metal layer. For more information on these options, see the *DESCRIPTION* section. To turn the rules on, you must use all of the following options: **-extension_width**, **-extension_space**, **-extension_count**, and **-extension_via_array**.

-extension_try_jog conn_length_threshold

Sets a threshold for the length of a connection. If the length of a segment in a connection is more than this value, the command tries to find a target in other directions to minimize the length of the connection.

The fB-extension_try_jog option is an extension option. To use it, you must also use all of the other extension options: **-extension_width**, **-extension_space**, **-extension_count**, and **-extension_via_array**.

-leave_space_for_io_connections

Specifies that the **create_power_straps** command should not create a strap extension in a location that could be used to connect I/O pads to a power ring.

You can set this option only if *both* of the following conditions are met:

- More than *min_count* (as specified in the **-extension_count** option) parallel connections might be created.
- The extension rules are turned on. To turn the rules on, you must use the following options: **-extension_width**, **-extension_space**, **-extension_count**, and **-extension_via_array**.

-resolve_conflicts_by_jogs

Causes the **preroute_instances** command to create a jogged connection instead of a direct connection when it connects an I/O pad to a power ring if the direct connection would cause a design rule checking (DRC) violation.

You can set this option only if the extension rules are turned on as described in the *DESCRIPTION* section. To turn the rules on, you must use all of the

following options: **-extension_width**, **-extension_space**, **-extension_count**, and **-extension_via_array**.

-connection_point_default {offset pitch}

Specifies the offset of the first via array from the low boundary of the target and the pitch between neighbor arrays. If the target is located on a layer specified in the **-connection_point_layers** option, then the values specified in the **-connection_points_offset** and **-connection_points_pitch** options override these values. The default value for the **-connection_point_default** option is given in the format {W/2 W}, where W is width of the target, so the *offset* value is determined by the formula W/2 and the *pitch* value is W.

This connection option controls one aspect of creating the coordinates for the center of the via arrays that connect a segment to a target for a specific layer. If you do not specify any of these options, vias are created as usual. For more information on control options, see the *DESCRIPTION* section. The control options are: **-connection_point_default**, **-connection_point_layers**, **-connection_point_offsets**, and **-connection_point_pitches**.

-connection_point_layers conn_pt_layers_list

Specifies a list of layers. If a target is located on a layer from this list, the offset and pitch for the connection points are taken from the **-connection_points_offset** and **-connection_points_pitch** options, respectively. Each layer is specified by its name.

This connection option controls one aspect of creating the coordinates for the center of the via arrays that connect a segment to a target for a specific layer. If you do not specify any of these options, vias are created as usual. For more information on control options, see the *DESCRIPTION* section. The control options are: **-connection_point_default**, **-connection_point_layers**, **-connection_point_offsets**, and **-connection_point_pitches**.

-connection_point_offsets offsets_list

Specifies the offset, as a list of distances, used for each layer specified in the **-connection_point_layers** option. If you do not specify the **-connection_point_offsets** option, the offset is taken from the **-connection_point_default** option. If the length of the list of offsets is less than number of layers specified in the **-connection_point_layers** option, the last value applies to the other layers.

This connection option controls one aspect of creating the coordinates for the center of the via arrays that connect a segment to a target for a specific layer. If you do not specify any of these options, vias are created as usual. For more information on control options, see the *DESCRIPTION* section. The control options are: **-connection_point_default**, **-connection_point_layers**, **-connection_point_offsets**, and **-connection_point_pitches**.

-connection_point_pitches pitches_list

Specifies the pitch, as a list of distances, for each layer specified in the **-connection_point_layers** option. If you do not specify the **-connection_point_pitches** option, the pitch is taken from the **-connection_point_default** option. If the length of the list of pitches is less than number of layers specified in the **-connection_point_layers** option, the last value applies to the other layers.

This connection option controls one aspect of creating the coordinates for the center of the via arrays that connect a segment to a target for a specific layer. If you do not specify any of these options, vias are created as usual.

For more information on control options, see the *DESCRIPTION* section. The control options are: **-connection_point_default**, **-connection_point_layers**, **-connection_point_offsets**, and **-connection_point_pitches**.

-first_strap_offset first_strap_offset

Specifies the offset of the first power strap created by the **create_power_straps** command. This information is used by the **create_power_straps -configure rows** command when the direction of the straps is the same as the direction of the placement rows. The value should be equal to the difference between central line of the first strap to be created and the low boundary of the first row. The default value is half of width of the strap.

-strap_endcap strap_endcap_distance

Specifies information used by the **create_power_straps -configure rows** command when the direction of the straps differs from the direction of the placement rows. It specifies the minimum extension of a strap over the boundary box of the rows. The default value is 0.

-create_local_straps min_dist_threshold

Specifies information used by the **create_power_straps -configure rows** command when the direction of the straps differs from the direction of the placement rows. It specifies the minimum distance from the end points of a row where at least one strap should be created. If there are no straps in that area, the tool must create additional local straps.

-keep_straps_in_standard_cell_area

Specifies information used by the **create_power_straps -configure rows** command when the direction of the straps differs from the direction of the placement rows. It controls whether straps can be broken by the areas that are not covered by placement rows. Usually, such areas are dedicated for macro cells.

-macro_cells {macro_cells_collection}

Specifies information used by the **create_power_straps -configure macros** command to determine which macro cells to create straps over. If you do not specify this option, straps are created over all macro cells in the design.

-pin_layer pin_layer_name

Specifies information used by the **create_power_straps -configure macros** command. It specifies the layer containing the pins for which straps are to be created. Straps are created only for the pins on the specified layer. This option is mandatory when the straps are configured by macro cells.

-strap_to_pin_offset strap_to_pin_offset

Specifies information used by the **create_power_straps -configure macros** command. It specifies the offset from the center line of the pin for which the strap is created to the center line of the created strap. The default value is 0.

-end_point_offset end_point_offset_distance

Specifies information used by the **create_power_straps -configure macros** command. It specifies the distance from the macro cell boundary to the end points of a strap before its extension (if it is required). The default value is 0.

```

-target_area {{dx-left dy-bottom} {dx-right dy-top}}
    Specifies information used by the create_power_straps -configure macros
    command. It specifies a rectangle where the straps are connected to a target.
    Coordinates of the rectangle are calculated as follows:
    X-left = macro_X_left - dx-left;
    Y-bottom = macro_Y_bottom - dy-bottom;
    X-right = macro_X_right + dx-right;
    Y-top = macro_Y_top + dy-top;
    If you do not specify this option, no connections are required. If you specify
    this option, the -target_layer option and at least one connection to a target
    in that area are required.

-target_layer target_layer_name
    Specifies information used by the create_power_straps -configure macros
    command. It specifies the name of the layer on which to search for targets.
    This option is required if you use the -target_area option.

-jog_horizontal_layers h_layers_list
    Specifies information used by the create_power_straps -configure macros
    command. It specifies a list of layers that can be used for the horizontal
    segments of jogged connections. The layers are specified by name. This option
    is required if jogged connections are allowed.

-jog_vertical_layers v_layers_list
    Specifies information used by the create_power_straps -configure macros
    command. It specifies a list of layers that can be used for vertical segments
    of jogged connections. The layers are specified by name. This option is
    required if jogged connections are allowed.

-jog_width {h_segments_width v_segments_width}
    Specifies information used by the create_power_straps -configure macros
    command. It specifies the width of the horizontal and vertical segments of
    jogged connections. By default, both the horizontal and vertical widths are
    equal to the width of a strap.

```

DESCRIPTION

This command creates a set of special rules that must be observed by the **create_power_straps** and **preroute_instances** commands. These commands refer to these special rules by the name specified in the **-name** option. You can specify as many sets of special rules as you want.

Extension Options

Several extension options control the geometries of power strap connections (created by the **create_power_straps** command) or I/O pads (created by the **preroute_instances** command) when it is impossible to make a connection by using only the primary metal layer. The extension options are the following:

- extension_width
- extension_space
- extension_count

```
-extension_via_array  
-extension_try_jog
```

Usually, these extension options are needed if the connected straps or pads have a much bigger width than the maximum width allowed on other metal layers and, so, redundant connections are required. To turn the rules on, you must specify all of the extension options, except **-extension_try_jog**.

Connection Options

Several connection options specify the coordinates for the center of via arrays that connect a segment to a target for a specific layer. If you do not specify any of these options, vias are created as usual. The connection options are the following:

```
-connection_point_default  
-connection_point_layers  
-connection_point_offsets  
-connection_point_pitches
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates power straps in the same direction (horizontal) as the direction of placement rows. The location of the first (bottom) strap is specified by an offset of its center line from the bottom boundary of the core area (that is, use the **-first_strap_offset 1.48** option). No vias should be dropped to connect any pins. The rules specify the following requirements for connecting end points of straps to targets when it is necessary to use segments on other metal layers:

- At least four parallel segments must be created on each of the M7, M5, and M3 layers (that is, use the **-extension_count {4 99}** option).
- Each of those segments must have a width equal to 1.5.
- The space between neighboring segments on the same layer must be equal to 0.5.
- A jogged connection is used when the length of a segment is more than 64.
- Via arrays connecting a strap with a segment must have a size of 6x2.
- If more than four parallel connections might be created on each layer, they are created if there are no I/O pads of other power and ground nets to connect in that area (that is, use the **-leave_space_for_io_connections** option).

```
prompt> set_preroute_special_rules -name specGS\  
-first_strap_offset 1.48\  
-do_not_connect_pins\  
 
```

```

-extension_layers {M7 M5 M3}\
-extension_width 1.5\
-extension_space 0.5\
-extension_count {4 99}\
-extension_via_array {6 2}\
-extension_try_jog 64\
-leave_space_for_io_connections

prompt> create_power_straps\
-nets {VSS VDD}\
-configure_rows\
-direction horizontal\
-layer PM\
-width 8.0\
-pitch_within_group 10.08\
-step 20.16\
-extend_low_ends_to_first_target\
-extend_high_ends_to_first_target\
-keep_floating_wire_pieces\
-ignore_parallel_targets\
-special_rules specGS

```

The following example creates power straps orthogonal to the placement row direction (vertical). No vias should be dropped to connect any pins. If a strap is located under or over a wide target (not a pin), the following special via rules are applied:

- The pitch of the via arrays should be equal to 6.96 and the offset of the first one (from the bottom boundary of the target) should be equal to 0.52.
- Straps are not created in areas if there are no placement rows (that is, use the **-keep_straps_in_standard_cell_area** option).
- Each strap is extended by 0.24 over the boundary of the first and last placement row in the area.

```

prompt> set_preroute_special_rules -name specLMVstd\
-do_not_connect_pins\
-connection_point_default {0.52 6.96}\
-straps_endcap 0.24\
-create_local_straps 14.15\
-keep_straps_in_standard_cell_area

prompt> create_power_straps\
-nets {VDD VSS}\
-configure_rows\
-direction vertical\
-layer M4\
-width 0.44\
-pitch_within_group 0.66\
-step 29.4\
-advanced_via_rules\
-extend_low_ends_to_first_target\
-extend_high_ends_to_first_target\

```

```
-do_not_route_over_macros\
-keep_floating_wire_pieces\
-ignore_parallel_targets\
-special_rules specLMVstd
```

The following example creates vertical power straps over a macro cell if it has pins on the M4 metal layer. The distance between the end points of a strap and the boundary of the macro cell should be equal to 0.57. If a strap is located under or over a wide target (not a pin), the following special via rules are applied:

- The pitch of the via arrays should be equal to 6.96.
- The offset of the first via array (from the bottom boundary of the target) should be equal to 0.52.

```
prompt> set_preroute_special_rules -name specLMVmem\
-end_point_offset 0.57\
-connection_point_default {0.52 6.96}\
-pin_layer M4
```

```
prompt> create_power_straps\
-nets {VDD VSS}\
-configure_macros\
-direction vertical\
-layer M4\
-advanced_via_rules\
-extend_low_ends off\
-extend_high_ends off\
-special_rules specLMVmem
```

The following example connects I/O pads to a ring. If it is necessary to use segments on other metal layers, the rules specify the following requirements for connections:

- At least eight parallel segments must be created on each of the M7, M5, and M3 metal layers (that is, use the **-extension_count {8 99}** option).
- Each of those segments must have width equal to 1.5.
- The space between neighboring segments on the same layer must be equal to 0.5.
- Via arrays connecting a pin with a segment must have a size of 20x2.
- If there are less than eight parallel connections on each layer, the additional ones should be created with jogs (that is, use the **-resolve_conflicts_by_jogs** option).

```
prompt> set_preroute_special_rules -name specIOhor\
-extension_layers {M7 M5 M3}\
-extension_width 1.5\
-extension_space 0.5\
-extension_count {8 99}\
-extension_via_array {20 2}\
```

```
-resolve_conflicts_by_jogs

prompt> preroute_instances \

[preroute_instances\(2\)](#)

set_primerime_options

Sets up PrimeTime options for the **signoff_opt** command.

SYNTAX

```
status set_primerime_options
[-default]
[-exec_dir string]
[-sdc_file string]
[-max_image string]
[-min_image string]
[-setup_slack_limit float]
[-hold_slack_limit float]
[-common_file string]
[-specific_file string]
[-license_limit integer]
```

ARGUMENTS

```
[-default]
    Resets all options to default.

[-exec_dir string]
    Specifies the UNIX path to the PrimeTime shell executable pt_shell. The path
    can be either relative or complete.

[-sdc_file string]
    Specifies the golden signoff SDC file for PrimeTime. This is an optional
    argument, and if it is missing, PrimeTime will use the constraints stored in
    the Milkyway.

[-max_image string]

[-min_image string]
    Specifies the saved session directory from a save_session command in
    PrimeTime. signoff_opt will load the session as max/min corner with
    restore_session, and continue optimization. Because the PrimeTime was run
    standalone, it is required that you must maintain the consistency between the
    PrimeTime run and IC Compiler, such as netlist, constraints and parasitic,
    when this switch is used. An inconsistent netlist, for example, PrimeTime's
    netlist has one more buffer than IC Compiler, can lead to unexpected results
    when running signoff_opt.

[-setup_slack_limit float]

[-hold_slack_limit float]
    Specifies the setup/hold slack limit for optimization, such that optimization
    will only work on the paths that have at least the specified slacks.

[-common_file string]
    Specifies a tcl file that will be sourced to PrimeTime immediately after
    PrimeTime is invoked. Only TCL variables are allowed in this file.
```

```
[-specific_file string]
    Specifies a tcl file that will be sourced to PrimeTime after loading the
    constraints. Only analysis commands are allowed in this file. For BCWC
    analysis, you can specify a list of two files.

[-license_limit integer]
    Specifies maximum number of PT/PTSI licenses that will be used. This option
    is only valid with multi mode multi corner analysis using PT DMSA.
```

DESCRIPTION

This command sets up PrimeTime options for **signoff_opt**. Use **report_primateime_options** command to examine the options.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example runs the **set_primateime_options** command.

```
prompt> open_mw_cel -lib my_lib my_cel
prompt> set_primateime_options\
-exec_dir /PrimeTime/linux/syn/bin
prompt> save_mw_cel
```

The following example use the **-setup_slack_limit** to tell IC Compiler to optimize paths that have at least -1ns slack.

```
prompt> set_primateime_options -setup_slack_limit -1
```

SEE ALSO

```
clock_opt(2)
place_opt(2)
report_primateime_options(2)
route_opt(2)
signoff_opt(2)
```

set_propagated_clock

Specifies propagated clock latency.

SYNTAX

```
string set_propagated_clock  
object_list
```

Data Types

object_list list

ARGUMENTS

object_list
Provides a list of clocks, ports, pins, or cells.

DESCRIPTION

Specifies that delays be propagated through the clock network to determine latency at register clock pins. If not specified, ideal clocking is assumed. Ideal clocking means clock networks have a specified latency (from the **set_clock_latency** command), or zero latency by default. Propagated clock latency is used for postlayout, after final clock tree generation. Ideal clock latency provides an estimate of the clock tree for prelayout.

If **set_propagated_clock** is applied to pins or ports, it affects all register clock pins in the transitive fanout of the pins or ports.

To undo **set_propagated_clock**, use **remove_propagated_clock** or **set_clock_latency** to provide an ideal latency.

To see propagated clock attributes on clocks, use **report_clock -skew**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

This example specifies to use propagated clock latency for all clocks in the design.

```
prompt> set_propagated_clock [all_clocks]
```

SEE ALSO

remove_propagated_clock(2)

set_propagated_clock

2590

```
set_clock_latency(2)
report_clock(2)
set_input_delay(2)
create_clock(2)
current_design(2)
```

set_pulse_clock_cell

Specifies the pulse type for a pulse clock cell with a single input and a single output.

SYNTAX

```
string set_pulse_clock_cell
-type pulse_type
object_list
```

Data Types

object_list list

ARGUMENTS

```
-type pulse_type
      Specifies the type of pulse clock applied to all library cells in object_list.
      The possible values for pulse_type are: rise_triggered_high_pulse,
      fall_triggered_high_pulse, rise_triggered_low_pulse,
      fall_triggered_low_pulse

object_list
      Lists of library cells which has the specified pulse type. It is required
      that the library cell has only one single input and one single output.
```

DESCRIPTION

This command gives user control to override the pulse type automatically inferred by the tool. However, it is not able to override the pulse type defined by library format.

To turn on this command functionality, please set variable timing_pulse_clock_cell_type_auto_inference to TRUE.

To check if an instance cell has mismatched pulse type defined from its library cell, please use check_timing_pulse_clock_cell_type options.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies a pulse type of fall_triggered_high_pulse for a library cell.

```
prompt> set_pulse_clock_cell -type fall_triggered_high_pulse {celllib/pulse_rise_high}
```

SEE ALSO

`check_timing(2)`

set_qtm_global_parameter

Sets a global parameter for quick timing models (QTMs).

SYNTAX

```
string set_qtm_global_parameter
[-param parameter]
[-lib_cell lib_cell]
[-pin pin_name]
[-clock pin_name]
[-value parameter_value]
```

Data Types

<i>parameter</i>	string
<i>lib_cell</i>	string
<i>pin_name</i>	string
<i>parameter_value</i>	float

ARGUMENTS

-param *parameter*
Specifies the global parameter you want to set. The global parameter can be setup, hold, or clk_to_output.

-lib_cell *lib_cell*
Specifies the lib_cell you want to use to mimic the global parameter.

-pin *pin_name*
Specifies the related pin for the global parameter if you are using lib_cell to mimic the behavior. If the parameter is setup/hold, this pin must be an input pin. If the parameter is clk_to_output, this pin has to be an output pin. If you do not use this option, QTM uses the first encountered input pin that is constrained, in case of setup/hold; and the first output pin which has an edge delay arc coming into it, in case of clk_to_output parameter.

-clock *pin_name*
Specifies the constraining pin in case of setup or hold; and the launch pin in case of clk_to_output parameter.

-value *parameter_value*
The value of the global parameter in time units.

DESCRIPTION

This command sets the value of a desired QTM global parameter. The global parameter can be either setup, hold, or clk_to_output. These parameters specify the global parameter which is added to the arcs. To the QTM setup arc, the time is added to arrive at the final delay. To the QTM hold arc, the global hold time is added to arrive at the final delay. To the QTM edge triggered delay arc the global clk_to_output time is added to arrive at the final delay.

You can specify the global parameters of the sequential element by specifying a cell in the library (**-lib_cell** option), or by giving the actual value, by using **-value** option. If the **-lib_cell** option is specified, you can specify the clock pin and the input pin name. If you do not specify one, the first setup, hold, or clk_to_output arc encountered is chosen (based on which parameter is being set). If only **-clock** option is specified, the first setup, hold, or clk_to_output arc (depending on the global parameter) from that clock pin is chosen. If only the **-pin** option is specified, the first setup, hold, or clk_to_output arc (depending on the type of global parameter) coming into the pin is chosen.

To show the information about the current QTM model, use **report_qtm_model** command.

For a basic description about QTM, please refer to **create_qtm_model** man page. For a more detailed description about QTM, please refer to Chapter 12 of the *ICC Design Planning User Guide*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

In the following examples where ever **-lib_cell** is used, you must have loaded the technology library and set the qtm technology set. This is done through the following sequence of commands:

```
read_db my_technology_library.db  
set_qtm_technology -library my_technology_library
```

The following example sets the global setup time equivalent to the setup time of DFF1.

```
prompt> set_qtm_global_parameter -param setup -lib_cell DFF1
```

The following example sets the global hold time equivalent to the setup time of pin D of DFF1.

```
prompt> set_qtm_global_parameter -param setup -lib_cell DFF1 -pin D
```

The following example sets the global clk_to_out time to be 1.5 time units.

```
prompt> set_qtm_global_parameter -param clk_to_output -value 1.5
```

```
set_qtm_global_parameter  
2596
```

set_qtm_port_drive

Sets the drive on quick timing model (QTM) ports.

SYNTAX

```
string set_qtm_port_drive
[-type drive_type]
[-value drive_value]
[-input_transition_rise rtrans]
[-input_transition_fall ftrans]
port_list
```

Data Types

<i>drive_type</i>	string
<i>drive_value</i>	float
<i>rtrans</i>	float
<i>ftrans</i>	float
<i>port_list</i>	list

ARGUMENTS

-type *drive_type*

Specifies the the global *drive_type* parameter with this option.

-value *drive_value*

Specifies the drive value in terms drive resistance units with this option.

-input_transition_rise *rtrans*

Specifies the input rising transition time associated with the **-input_pin** of the specified drive type to compute the delay for the drive arc for this port. If you do not include this option, the delay table for rising input of the drive arc will be loaded from library as is.

Use the **-input_transition_rise** and **-input_transition_fall** options to capture the transition time associated with the *input_pin* defined for the drive type referred. This can obtain more accurate information on the transition time and delay time for the drive arc to be defined for this port.

-input_transition_fall *ftrans*

Specifies the input falling transition time associated with the *input_pin* of the specified drive type to compute the delay for the drive arc for this port. If you do not include this option, the delay table for falling input of the drive arc will be loaded from library as is.

port_list

Specifies a list of input or inout ports on which to set the attribute. Each element in the list is either a collection of QTM ports or a pattern which matches QTM ports.

DESCRIPTION

This command sets the drive of the output port of the QTM model. There are two methods for setting the drive:

1. Use one the global `drive_type`, if you have drive types defined.
2. Define the drive in terms of the drive resistance units.

Define drive types by using the command `create_qtm_drive_type`.

To show the information about the current QTM model, use the `report_qtm_model` command.

For a basic description about QTM, please refer to `create_qtm_model` man page. For a more detailed description about QTM, please refer to the *ICC Design Planning User Guide*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command sets the drive of output port OUT1 to be of `drive_type` drive1.

```
prompt> set_qtm_port_drive -type drive 1 OUT1
```

The following command sets the drive of the output port OUT2 to be 5 drive units.

```
prompt> set_qtm_port_drive -value 5.0 OUT2
```

SEE ALSO

`create_qtm_load_type(2)`
`create_qtm_model(2)`
`report_qtm_model(2)`
`save_qtm_model(2)`
`set_qtm_port_load(2)`

set_qtm_port_load

Sets the load on quick timing model (QTM) ports.

SYNTAX

```
string set_qtm_port_load
[-type load_type]
[-factor multiplication_factor]
[-value load_value]
port_list
```

Data Types

<i>load_type</i>	string
<i>multiplication_factor</i>	float
<i>load_value</i>	float
<i>port_list</i>	list

ARGUMENTS

-type *load_type*
Specifies the global *load_type* parameter.

-factor *multiplication_factor*
Specifies the multiplication factor for the load type to set the load on the QTM port.

-value *load_value*
Specifies the load value in the capacitance units.

port_list
Specifies a list of input or inout ports on which to set the attribute. Each element in the list is either a collection of QTM ports or a pattern that matches QTM ports.

DESCRIPTION

This command sets the load of the input port of the QTM model. There are two methods for setting the load:

1. Use the global *load_type* along with a multiplication factor if you have load types defined.
2. Define the load in terms of the capacitance units.

Define load types using the command **create_qtm_load_type**.

To show the information about the current QTM model, use the **report_qtm_model** command.

For a basic description about QTM, please refer to **create_qtm_model** man page. For a more detailed description about QTM, please refer to the *ICC Design Planning User*

Guide.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command sets the load on IN1 to be 2 times the global load_type load1.

```
prompt> set_qtm_port_load -type load1 -factor 2 IN1
```

The following command sets the load on IN2 to be 4.5 capacitance units.

```
prompt> set_qtm_port_load -value 4.5 IN2
```

SEE ALSO

```
create_qtm_load_type(2)  
create_qtm_model(2)  
report_qtm_model(2)  
save_qtm_model(2)  
set_qtm_port_drive(2)
```

set_qtm_port_load
2600

set_qtm_technology

Sets quick timing model technology variables.

SYNTAX

```
string set_qtm_technology
[-library name]
[-max_transition max_trans_value]
[-min_transition min_trans_value]
[-max_capacitance max_cap_value]
[-min_capacitance min_cap_value]
[-wire_load_model wlm_name]
[-process process_value]
[-voltage voltage_value]
[-temperature temperature_value]
```

Data Types

<i>name</i>	string
<i>max_trans_value</i>	float
<i>min_trans_value</i>	float
<i>max_cap_value</i>	float
<i>min_cap_value</i>	float
<i>wlm_name</i>	string
<i>process_value</i>	float
<i>voltage_value</i>	float
<i>temperature_value</i>	float

ARGUMENTS

-library *name*

Specifies the library name for using library elements to define global parameters. The library is the timing library in the Synopsys data base (.db) file, not the Milkyway reference or design library. Substitute the string value you want for *name*.

-max_transition *max_trans_value*

Specifies the maximum transition value to use. You must express it in units consistent with those in the technology library used during optimization. For example, if the library specifies drive values in kilohms and load values in picofarads, then you must express *max_transition_value* in nanoseconds. Substitute the float value you want for *max_trans_value*.

-min_transition *min_trans_value*

Specifies the minimum transition value to use. You must express it in units consistent with those in the technology library used during optimization. For example, if the library specifies drive values in kilohms and load values in picofarads, then you must express *min_transition_value* in nanoseconds. Substitute the float value you want for *min_trans_value*.

-max_capacitance *max_cap_value*

Specifies the maximum value to use for capacitance. You must express it in

units consistent with the technology library used during optimization. For example, if the library specifies capacitance values in picofarads, then you must express *max_cap_value* in picofarads. Substitute the float value you want for *max_cap_value*.

-min_capacitance *min_cap_value*

Specifies the minimum value to use for capacitance. You must express it in units consistent with the technology library used during optimization. For example, if the library specifies capacitance values in picofarads, then you must express *min_cap_value* in picofarads. Substitute the float value you want for *min_cap_value*.

-wire_load_model *wlm_name*

Specifies the wire load model to use when calculating delays. Substitute the string value you want for *wlm_name*.

-process *process_value*

Specifies the process scaling factor for the default operating condition of the quick timing model in an MCMM design. When you want to use any of the following options, you must use all of them: **-operating_condition**, **-process**, **-voltage**, and **-temperature**. Allowed values are 0.0 through 100.0.

-voltage *voltage_value*

Specifies the voltage value, in Volts, for the default operating condition of the quick timing model in an MCMM design. When you want to use any of the following options, you must use all of them: **-operating_condition**, **-process**, **-voltage**, and **-temperature**.

-temperature *temperature_value*

Specifies the temperature value, in degrees Celsius, for the default operating condition of the quick timing model in an MCMM design. When you want to use any of the following options, you must use all of them: **-operating_condition**, **-process**, **-voltage**, and **-temperature**.

DESCRIPTION

This command sets various quick timing model technology parameters. You can use the **-library** option to define path types, drive types, and load types, or if you set the other global parameters in terms of library cells. Before setting the library, you ensure that it is loaded.

If you have set the wire load model, the path type delays are calculated by using that wire load model.

You can use the **report_qtm_model** command to show information about the current quick timing model.

For a basic description of quick timing models, see the **create_qtm_model** man page. For a more detailed description of quick timing models, see *Creating Quick Timing Models for Black Boxes in IC Compiler User Guide: Design Planning Contents*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets the library to the name my_lib.

```
prompt> read_db my_lib.db
#my_lib.db contain the library my_lib
prompt> set_qtm_technology -library my_lib
```

The following command sets the wire_load_model to the name wlm1.

```
prompt> set_qtm_technology -wire_load wlm1
```

SEE ALSO

```
create_qtm_model(2)
report_qtm_model(2)
save_qtm_model(2)
```

set_rail_options

Specifies setup options for the **analyze_rail** command.

SYNTAX

```
status set_rail_options
[-default]
[-output_dir dir_name]
[-use_pins_as_pads true | false]
[-pad_master_file file_name]
[-pad_instance_file file_name]
[-user_defined_tap_file file_name]
[-packaging_file file_name]
[-vd_threshold value]
[-switching_activity {type file_name strip_path}]
[-host machine_name]
[-pr_exec_dir dir_name]
[-pt_exec_dir dir_name]
[-sdc file_name]
[-spf file_name]
[-verilog file_name]
[-upf file_name]
```

Data Types

<i>dir_name</i>	string
<i>file_name</i>	string
<i>value</i>	float
<i>type</i>	string
<i>strip_path</i>	string
<i>machine_name</i>	string

ARGUMENTS

```
-default
    Resets all the options to the default setting for the PrimeRail analysis flow.

-output_dir dir_name
    Specifies the output directory for the analyze_rail command. By default, the
    PrimeRail output directory is named ./pr_current_cell_name in the working
    directory. The directory contains the following contents:
    1. synopsys_rail_setup/
        Data output from IC Compiler for running PrimeRail
    2. rail_map_data/
        PrimeRail map data to be viewed in IC Compiler GUI
    3. analyze_rail.cmd      The script of the PrimeRail run
    4. analyze_rail.log      The log file of the PrimeRail run
    5. Error text report files: current_cell_name_net_name_analysis_type_err.t
xt
    6. Others files like PrimeRail and PrimeTime PX run scripts, intermediate
files and so on.
```

-use_pins_as_pads true | false
Treats the top-level P/G pins as the ideal voltage sources in the block-level simulation. The default value is true.

-pad_master_file file_name
Specifies an optional pad master file name, which specifies Milkyway pad master cells to be used as ideal voltage sources for rail analysis. You can optionally specify a given cell to be treated as a pad master only when analyzing certain P/G nets. If you do not specify the net name, the command assumes the specified pad master is used for all nets being analyzed. The following is the format to specify master names and net names:
master_name [net_name]
For example, *VDD.FRAM VDD* is a valid *master_name [net_name]* value.

-pad_instance_file file_name
Specifies an optional pad instance file name, which specifies Milkyway pad cells instances to be used as ideal voltage sources for rail analysis. You can optionally specify a given cell to be treated as a pad instance only when analyzing certain P/G nets. If you do not specify the net name, the command assumes the specified pad instance is used for all nets being analyzed. The following is the format used to specify instance names and net names:
instance_name [net_name]
For example, a valid *instance_name [net_name]* might be *VDD1 VDD*.

-user_defined_tap_file file_name
Specifies an optional file that defines the physical location (coordinates, layer numbers) of the ideal voltage sources to be used in the rail analysis. This is useful when you are working with a block or a design that does not yet have pins defined, or the location or the design of the pad cells is not yet finalized. This ASCII file that specifies the ideal voltage source coordinates and layer numbers in the following format:
netName layerNumber xCoord yCoord
The coordinates are in microns. For instance, if you want to apply the ideal voltage of VDD net on layer 3 at three locations, create the file with the following lines:
VDD 3 784.000 1826.000
VDD 3 1184.000 1826.000
VDD 3 1584.000 1826.000

-packaging_file file_name
Specifies an optional SPICE file containing packaging parasitics to be analyzed with the chip together.

-vd_threshold value
Specifies the voltage drop threshold in mV for violation checking. When not specified, the tool sets the threshold to 0.0 (the default) and does not generate a voltage drop violation report.

-switching_activity {type file_name strip_path}
Specifies an optional switching activity file to be used in rail analysis. Otherwise, the default toggle rate will be used.
This file can be in either VCD or SAIF format. These files are often generated

by simulation tools that are using a different top-level design than the IC Compiler session, so the optional `strip_path` provides a mechanism to remove the portion of the included object names not represented in IC Compiler. For example,

```
-switching_activity {VCD top_design.vcd /top_design/cup_module}
Executing the above line loads in a VCD file and strips the prefix /  
top_design/cup_module from all object names.
```

For VCD activity files, rail analysis will be performed across all time values included in the file.

-host *machine_name*

Specifies a computer host name for running PrimeRail on a different machine. By default, PrimeRail is run on the same machine on which the current IC Compiler session is running.

-pr_exec_dir *dir_name*

Specifies the path to the PrimeRail binary. By default, IC Compiler locates the binary via the UNIX search path.

-pt_exec_dir *dir_name*

Specifies the path to the PrimeTime binary. By default, IC Compiler locates the binary via the UNIX search path.

-sdc *file_name*

Specifies an optional SDC script file. When not specified, an SDC script file is created based on the data saved in Milkyway database.

-spef *file_name*

Specifies an optional parasitic SPEF file. When not specified, a parasitic SPEF file is created based on the data saved in Milkyway database.

-verilog *file_name*

Specified an optional Verilog netlist file. When not specified, a Verilog netlist file is created based on the data saved in Milkyway.

-upf *file_name*

Specified an optional UPF script file. When not specified, a UPF script file is created based on the data saved in Milkyway.

DESCRIPTION

This command specifies options for executing the **analyze_rail** command. If this command is not run, **analyze_rail** will be run using the default set of options. For example, the PrimeRail run directory is set to `./pr_current_mw_cell/` under the working directory and the `-use_pins_as_pads` option is enabled.

The following four options are for full-chip analysis and they have been together with the following legal combinations:

- o NO -sdc, no -spef, no -verilog, no -upf
- o -sdc plus -spef
- o -sdc plus -spef plus (-verilog or -upf)
- o -sdc plus -spef plus -verilog plus -upf

Otherwise, the **analyze_rail** command will stop and return an error.

EXAMPLE

The following example resets all the options to the default setting:

```
prompt> set_rail_options -default
```

The following example sets ideal voltage sources to the user-defined taps:

```
prompt> set_rail_options -user_defined_tap vdd_tap.txt
```

SEE ALSO

[report_rail_options\(2\)](#)
[analyze_rail\(2\)](#)

set_register_merging

Sets the **register_merging** attribute on the specified cells or designs, allowing register merging optimization on the objects.

SYNTAX

```
status set_register_merging
obj_list
[true | false]
```

Data Types

obj_list list

ARGUMENTS

obj_list

Specifies a list of cell or design names for which to enable register merging optimization. Cell names in *obj_list* must be from the current design. If multiple objects are specified, they must be enclosed in quotation marks ("") or braces ({}).

true | false

Specifies the value with which to set the **register_merging** attribute. When this option is set to true (the default), register merging is enabled.

DESCRIPTION

The **set_register_merging** command sets the **register_merging** attribute on the specified *obj_list*. This attribute is used to specify the cells or designs to be optimized using register merging.

If a cell with a specified name is found in the current design, the **register_merging** attribute is set to the specified value in the cell. If no cell with a specified name is found, the tool searches for a design and the attribute set for the design.

EXAMPLES

The following example shows how to enable register merging optimization during optimization for the sequential cells named *U0* and *U1* and how to disable register merging for the cell named *U2*:

```
prompt> set_register_merging {U0 U1} TRUE

set_register_type

Sets the **latch_type** or **flip_flop_type** attributes on designs or cell instances, to specify which sequential cells from the target library are to be used by the **compile** command.

SYNTAX

```
int set_register_type
-latch example_latch -exact |
-flip_flop example_flip_flop [-exact]
[cell_or_design_list]
```

Data Types

<i>example_latch</i>	string
<i>example_flip_flop</i>	string
<i>cell_or_design_list</i>	list

ARGUMENTS

-latch *example_latch*
Specifies a latch to be used by the **compile** command as the default latch type.
You can specify both **-latch** and **-flip-flop**, but you must specify at least one.

-exact
Instructs the **compile** command to make an exact mapping to the specified *example_latch* or *example_flip-flop*, if possible.
This argument is required when using the **-latch** argument.

-flip_flop *example_flip_flop*
Specifies a flip-flop from the target library to be used by the **compile** command as the default flip-flop type. the *example_flip_flop*, if possible.
This argument sets the **default_flip_flop_type** or
default_flip_flop_type_exact attribute to the *example_flip_flop* on all designs in *cell_or_design_list*; and the **flip_flop_type** or
flip_flop_type_exact attribute to the *example_flip_flop* on all cells in *cell_or_design_list*.
You can specify both **-latch** and **-flip-flop**, but you must specify at least one.

cell_or_design_list
Specifies a list of cells or designs in which to use the latch or flip-flop.
The default is the current design.

DESCRIPTION

Specifies latch or flip-flop type information for the **compile** command to use, by setting appropriate attributes on the designs or cell instances. For designs, specifying **-flip_flop** without **-exact**, sets the **default_flip_flop_type** attribute to *example_flip_flop*, indicating to use it as the default flip-flop type for those designs. And specifying **-exact -flip_flop** sets the **default_flip_flop_type_exact** attribute to *example_flip_flop*, indicating to use it as the exact default flip-flop

for those designs.

For example, to set the default flip-flop type for a design to be a D flip-flop, specify the name of any D flip-flop in the target library as the `example_flip_flop`, without `-exact`. If you specify `-exact`, the `example_flip_flop` is interpreted as the exact flip-flop to use.

Similarly, for cell instances, specifying `-flip_flop` without `-exact` sets the `flip_flop_type` attribute to `example_flip_flop`, indicating that it is to be used as the specific flip-flop type for those cells. And specifying `-exact -flip_flop` sets the `flip_flop_type_exact` attribute to `example_flip_flop`, indicating that it is to be used as the exact flip-flop for those cells.

When specifying a latch, you must always use the `-exact` option, so the `example_latch` is always the exact latch used as the default latch for designs and as the specific latch for cells. The `default_latch_type_exact` attribute is set to the specified latch on designs, and the `latch_type_exact` attribute is set to the specified latch on cells.

There are no `latch_type` or `default_latch_type` attributes.

The mapping process for flip-flops and latches consists of two steps:

1. Sequential gates are mapped to an initial latch or flip-flop from the target library. The `compile` command attempts to convert flip-flops or latches tagged by `set_register_type` to the specified flip-flop or latch type. Untagged sequential components are mapped to the default latch or flip-flop type if specified. In the absence of attributes on a design, or a sequential cell instance to control the mapping, the smallest area-cost flip-flop or latch is chosen.
2. If a flip-flop is not specified with the `-exact` option, the tool attempts to individually remap it to a lower-cost component from the target library. If `compile` cannot use the sequential component specified, or if no default flip-flop or latch is specified, `compile` maps these cells into the smallest sequential component possible.

A cell instance can have either latch or flip-flop attributes, but not both. Only latch cells can have latch attributes, and only flip-flop cells can have flip-flop attributes. Designs can have both latch and flip-flop attributes, because these attributes designate the default latch type (for latches in the design) and the default flip-flop type (for flip-flops in the design).

Unmapped sequential components can result when the `translate` command cannot find a close match for a flip-flop or latch in the new target library, or when latches or flip-flops are added to a design by HDL Compiler, VHDL Compiler, or state-machine software.

The `set_register_type` command constrains the mapping process. It does not constrain scan replacement in `insert_scan` or in `compile`.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the default flip-flop type for the current design to a D flip-flop, and that one example of a D flip-flop in the current library is the component *DFLOP*. This sets the **default_flip_flop_type** attribute to *DFLOP* on the current design. As a result, the default flip-flop used in mapping components that are not otherwise tagged is a D flip-flop.

```
prompt> set_register_type -flip_flop DFLOP
```

The following example sets the default flip-flop type for the current design exactly to the *DFLOP* cell. This sets the **default_flip_flop_type_exact** attribute to *DFLOP* on the current design. As a result, the default flip-flop used in mapping components that are not otherwise tagged is *DFLOP*.

```
prompt> set_register_type -exact -flip_flop DFLOP
```

The following example sets the default latch type for *FOO* and *BAR* designs to exactly a *DLATCH* gate. The **compile** command attempts to map all unmapped latches in these designs to *DLATCH*. This sets the **default_latch_type_exact** attribute to *DLATCH* on the *FOO* and *BAR* designs. The presence of this attribute indicates that an exact mapping is to be attempted for the *DLATCH* latch on the untagged cells in the *FOO* and *BAR* designs. Sequential types for latches must always be set as exact.

```
prompt> set_register_type -exact -latch DLATCH {FOO, BAR}
```

The following example maps a group of cell instances exactly to the *DLATCH* latch. This sets the **latch_type_exact** attribute on the *U1*, *U2*, and *U3* cell instances to the name *DLATCH*.

```
prompt> set_register_type -exact -latch DLATCH {U1, U2, U3}
```

The following example specifies the exact default latch type for the current design as *DLATCH* and the exact default flip-flop type as *DFLOP*. This sets the **default_latch_type_exact** attribute to the name *DLATCH* and the **default_flip_flop_type_exact** attribute to the name *DFLOP* on the current design so that **compile** can map otherwise untagged components in the design. You must use **-exact** when you specify both **-latch** and **-flip_flop** in the same command.

```
prompt> set_register_type -exact -latch DLATCH -flip_flop DFLOP
```

set_related_supply_net

Associates an external supply net to the port of the design.

SYNTAX

```
status set_related_supply_net
[supply_net_name]
[-object_list objects]
[-reset]
[-ground ground_net_name]
[-power power_net_name]
```

Data Types

<i>supply_net_name</i>	string
<i>objects</i>	list
<i>ground_net_name</i>	string
<i>power_net_name</i>	string

ARGUMENTS

supply_net_name

Specifies the name of the power net. This is deprecated and supported for backward compatibility only. New scripts should specify the power net using -power option.

-object_list objects

Specifies the list of ports to be associated with power/ground nets or reset. If this option is not specified, all the ports are considered.

-reset

Resets the related power and ground nets of the ports specified in object_list. This can't be used in conjunction with -power or -ground options

-ground ground_net_name

Specifies the name of the ground net.

-power power_net_name

Specifies the name of the power net.

DESCRIPTION

This command is used to associate supply nets with design ports. The tool uses this information for constraining and checking design. The level shifter insertion tool also uses supply nets to determine if level shifter is required between a port and the logic connected to the port.

If this command is not specified, the tool assumes that ports are externally connected to the primary supply net of the domain of the top design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the *VDD_EXT* power net and *VSS_EXTfp* ground net with *INPUT* port.

```
prompt> set_related_supply_net -object_list\
[get_ports INPUT] -power VDD_EXT -ground VSS_EXT
```

This example resets the power net and ground net on all ports.

```
prompt> set_related_supply_net -reset
```

SEE ALSO

`get_ports(2)`

set_relative_always_on

Sets the relative always-on relationship between power domains.

SYNTAX

```
status set_relative_always_on
domain_name
[-relative_to list_of_domains]
```

Data Types

<i>domain_name</i>	string
<i>list_of_domains</i>	list

ARGUMENTS

domain_name

Specifies the name of a relatively-more always-on power domain.

-relative_to *list_of_domains*

Specifies 1 or more power domains that are relatively-less always-on with respect to the domain specified using *domain_name*.

DESCRIPTION

This command creates relative always-on relationships between domains. The tool extracts power sequencing behavior between various domains based on the relationship specified by using this command. The information is used for checking isolation requirements on nets crossing domains.

For an example of how the tool uses a relative always-on relationship between domains consider the following scenario:

If domain A is more always-on than domain B and if an isolation cell on a net drives domain B from A, then the tool can flag this isolation cell as redundant.

The isolation cell is flagged as redundant because domain A will be on when domain B is on, so no isolation is required. Conversely, if there is no isolation cell connected to a net that drives domain A from B, then the tool can flag this as an error condition. The error results because when domain B is off, domain A is on, which might create a floating net condition.

EXAMPLES

The following example sets the PD1 power domain to be more always-on with respect to power domains PD2 and PD3:

```
prompt> set_relative_always_on PD1 B-relative_to {PD2 PD3}
1
```

set_relative_always_on
2614

SEE ALSO

`remove_power_domain(2)`
`report_power_domain(2)`

set_resistance

Sets the resistance value on nets.

SYNTAX

```
int set_resistance
value
[-min] [-max] net_list
```

Data Types

value	float
net_list	list

ARGUMENTS

value

Specifies the resistance value for nets in *net_list*. *value* must be expressed in unit system consistent with what the technology library used during optimization. For example, if the technology library specifies resistance values in ohms, *value* must also be expressed in ohms.

-min

Indicates that the resistance value is to be used for minimum delay analysis. If you do not specify a value for minimum delay analysis, the maximum value is used. If you do not specify a value for maximum delay analysis, the minimum value is ignored. (You cannot annotate only a minimum value.)

-max

Indicates that the resistance value is to be used for maximum delay analysis. If you do not specify **-min** or **-max**, the value is used for both minimum and maximum delay analysis.

net_list

Specifies a list of nets for which the specified resistance values are to be set.

DESCRIPTION

Sets the **ba_net_resistance** attribute, which enables the back-annotation of resistance values on nets in the current design. If the current design is hierarchical, it must have been linked with the **link** command. The specified *value* overrides the internally-estimated net resistance value.

You also can use the **set_resistance** command for nets at lower levels of the design hierarchy. These nets are specified as "BLOCK1/BLOCK2/NET_NAME."

To view resistance values, use the **report_net** command.

To remove a resistance value, use **remove_attribute**. To reset all back-annotated resistance values in a design, use the **reset_design** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets a resistance of 200 units to nets "a" and "b".

```
prompt> set_resistance 200 {a b}
```

This example sets a resistance of 300 units on net "U1/U2/NET3".

```
prompt> set_resistance 300 U1/U2/NET3
```

This example removes the back-annotated resistance on net "U1/U2/NET3".

```
prompt> remove_attribute [get_nets U1/U2/NET3] ba_net_resistance
```

SEE ALSO

set_retention

Defines the UPF retention strategy for the power domains in the design. This command is supported only in UPF mode.

SYNTAX

```
status set_retention
retention_strategy
-domain power_domain
-retention_power_net retention_power_net
-retention_ground_net retention_ground_net
[-elements objects]
```

Data Types

retention_strategy	string
power_domain	string
retention_power_net	string
retention_ground_net	string
objects	list

ARGUMENTS

retention_strategy
Specifies the UPF retention strategy name. The retention strategy name should be unique within the specified power domain.

-domain power_domain
Specifies the name of the power domain to which to apply this UPF retention strategy.

-retention_power_net retention_power_net
Specifies the retention power net for the retention cells that will be under this UPF retention strategy.

-retention_ground_net retention_ground_net
Specifies the retention ground net for the retention cells that will be under this UPF retention strategy.

-elements objects
Specifies the objects to which this UPF retention strategy applies. The objects can be hierarchical cells, leaf cells, HDL blocks, and nets.

DESCRIPTION

This command defines the UPF retention strategy on the specified power domain under which to map the unmapped sequential cells to retention cells.

If the **-elements** option is not specified, then the retention strategy will be applied to all of the unmapped sequential cells under the power domain. If **-elements** is specified, the UPF retention strategy will be applied to all of the unmapped

sequential cells that are under the objects from **-elements**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to define a UPF retention strategy in the specified power domain PD1. Power domain PD1 is defined on instance shutdown_inst.

```
prompt> set_retention retention_1\  
-domain PD1\  
-retention_power_net PN1 B\  
-retention_ground_net GN1
```

The following example shows how to define a UPF retention strategy in the objects under the specified power domain:

```
prompt> set_retention retention_2\  
-domain PD1\  
-retention_power_net PN1\  
-retention_ground_net GN1\  
-elements shutdownm_inst/mid_inst
```

SEE ALSO

[map_retention_cell\(2\)](#)
[set_retention_control\(2\)](#)

set_retention_control

Defines the UPF retention control signals for the defined UPF retention strategy. This command is supported only in UPF mode.

SYNTAX

```
status set_retention_control
retention_strategy
-domain power_domain
-save_signal {save_signal high | low}
-restore_signal {restore_signal high | low}
```

Data Types

<i>retention_strategy</i>	string
<i>power_domain</i>	string

ARGUMENTS

retention_strategy
Specifies the UPF retention strategy name. The retention strategy should have already been defined using **set_retention** command

-domain power_domain
Specifies the power domain name to which this UPF retention strategy is applied.

-save_signal {save_signal high | low}
Specifies the save signal and the save signal sense for the retention cells under this retention strategy.

-restore_signal {restore_signal high | low}
Specifies the restore signal and the restore sense for the retention cells under this retention strategy.

DESCRIPTION

This command defines the UPF retention control signals and control signal sense for this retention strategy of this power domain. The specified control signals are applied to the retention cells under the associated retention strategy.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to define the retention control signals on the defined UPF retention strategy *retention_1* of the power domain *PD1*.

```
prompt> set_retention_control retention_1 \
-domain PD1 \
-save_signal {save_net high} \
-restore_signal {restore_net low}
```

SEE ALSO

`map_retention_cell(2)`
`set_retention(2)`

set_route_flip_chip_options

Sets flip-chip router options.

SYNTAX

```
status set_route_flip_chip_options
[-number_of_loops 1 | 2 | 3]
[-route_with_soft_macros true | false]
[-search_effort easy | normal | hard]
[-layer_spacing {layer_spacing_pairs}]
[-layer_width {layer_width_pairs}]
[-rule_name name]
[-nets | -nets_in_file nets_file]
[-output_unrouted_nets open_net_file]
[-
design_style area_IO | peripheral_without_corner_driver | peripheral_with_corner_driver]
[-min_access_edge_length length]
```

Data Types

<i>layer_spacing_pairs</i>	string	float
<i>layer_width_pairs</i>	string	float
<i>name</i>	string	
<i>collection_of_nets</i>	collection	
<i>nets_file</i>	string	
<i>open_net_file</i>	string	
<i>length</i>	float	

DATA TYPES

<i>layer_spacing_pairs</i>	string	float
<i>layer_width_pairs</i>	string	float
<i>name</i>	string	
<i>collection_of_nets</i>	collection	
<i>nets_file</i>	string	
<i>layer</i>	string	
<i>open_net_file</i>	string	
<i>length</i>	float	

ARGUMENTS

-number_of_loops 1 | 2 | 3

Specifies the number of loops to route all the target nets. The default is 1.

-route_with_soft_macros true | false

Controls whether CEL view macro cells are treated as soft macros, which means that the cell area is blocked, except for pin access. When true, you do not have to convert the CEL view to a FRAM view before routing.

If you have a CEL view from custom editing, you might need to turn this option off so the IC Compiler shape-based router can read the internal blockages of

the macro cell or create a FRAM view for this custom-created macro. In any case, you can choose to create FRAM views for macros and use them in the design for ultimate control of the blockages.

The default is false.

-search_effort easy | normal | hard

Controls the router's search effort.

Use medium effort (the default), unless your design is complex or congested. Setting the search effort to high makes the router take longer to find a path. Set the effort to a higher level if you want the router to find a path for connecting nets. When performing an engineering change order, you might want to consider a higher level for routing the few remaining nets in a large design.

The default is medium.

-layer_spacing {*layer_spacing_pairs*}

Specifies the minimum spacing rules for each metal layer. The format is
{m1 *spacing1* m2 *spacing2* m3 *spacing3* ...}

By default, the router uses the minimum spacing specified in the technology file.

-layer_width {*layer_width_pairs*}

Specifies the minimum width rules for each metal layer. The format is
{m1 *width1* m2 *width2* m3 *width3* ...}

By default, the router uses the minimum width specified in the technology file.

-rule_name *name*

Specifies the rule to use for metal spacing and width. This option is required when you use the **-layer_spacing** or **-layer_width** options.

-nets {*collection_of_nets*}

Specifies the nets to be routed.

By default, all flip-chip nets are routed.

This option and the **-nets_in_file** option are mutually exclusive.

-nets_in_file *nets_file*

Specifies the name of a file that contains the list of nets to be routed.

This option and the **-nets** option are mutually exclusive.

-output_unrouted_nets *open_net_file*

Specifies the name of a file to which to write the unrouted nets.

By default, the unrouted nets are not output.

-design_style area_IO | peripheral_without_corner_driver |
peripheral_with_corner_driver

Specifies that design style.

The default is **peripheral_without_corner_driver**.

-min_access_edge_length *length*

Honor Minimum Access Length Rule: the bump-accessing & driver-accessing wires have min-length to follow.

The default value is 0 um.

DESCRIPTION

This command sets the options for flip-chip routing. It does not actually invoke any routing. It only allows you to specify options that are stored in the design database for use by subsequent flip-chip router steps.

EXAMPLES

The following example sets options to prepare for the flip-chip routing.

```
prompt> set_route_flip_chip_options \
    -number_of_loops 1 \
    -route_with_soft_macros false \
    -search_effort high \
    -layer_spacing {m8 2.5 m9 5} \
    -layer_width {m8 5 m9 5} \
    -rule_name rdlRule \
    -nets_in_file RDLNetFile \
    -routing_layer m9 \
    -output_unrouted_nets openNetFile \
    -design_style peripheral_with_corner_driver
```

SEE ALSO

optimize_flip_chip_route(2)
```

set_route_mode_options

To set the mode for running zroute.

SYNTAX

```
status set_route_mode_options
[-zroute true | false]
```

ARGUMENTS

```
-zroute true | false
    Specifies whether to run zroute.
    The default is false.
```

DESCRIPTION

The **set_route_mode_options** command sets the mode to run zroute.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the **-zroute** option to true.

```
prompt> set_route_mode_options -zroute true
```

SEE ALSO

set_route_opt_strategy

Sets the nonpersistent options that influence route_opt.

SYNTAX

```
status set_route_opt_strategy
[-default]
[-fix_hold_mode all | route_base]
[-xtalk_reduction_loops loop_count]
[-route_run_time_limit run_time]
[-search_repair_loops detail_loop_count]
[-optimize_wire_via_search_repair_loops optimize_loop_count]
[-route_drc_threshold threshold]
[-eco_route_search_repair_loops eco_routing_loop_count]
```

Data Types

<i>loop_count</i>	integer
<i>run_time</i>	integer
<i>detail_loop_count</i>	integer
<i>optimize_loop_count</i>	integer
<i>threshold</i>	integer
<i>eco_routing_loop_count</i>	integer

ARGUMENTS

-default
Resets all route_opt strategies to the default value.

-fix_hold_mode all | route_base
Specifies to hold fix flow inside route_opt. Inside route_opt are three different stages to fix hold: pre-route, global route, and detail route. The **all** argument specifies all mode, in which route_opt runs all three stages of hold fix optimizations. The **route_base** argument specifies **route_base** mode, in which route_opt runs only global route and detail route base hold fix optimization. The default is route_base.

-xtalk_reduction_loops loop_count
Specifies the number of crosstalk reduction optimization iterations. When the **route_opt** command is run with the **-effort high** option, then, by default the **set_route_opt_strategy** command uses **3**. When the **route_opt** command is run with the **-effort medium** option, then, by default the **set_route_opt_strategy** command uses **2**.

-route_run_time_limit run_time
Specifies the runtime limitation in minutes on optimize_wire_via routing. The default is no limit. This option cannot be used with set_route_opt_strategy in Zroute mode.

-search_repair_loops detail_loop_count
Specifies the number of search and repair loops in detail routing. If using Zroute, it overrides the -max_number_iterations droute option during initial

route. The default is **15** for ICC router and **10** for Zroute.

-optimize_wire_via_search_repair_loops optimize_loop_count
 Specifies the number of search and repair loops in optimizing wire via. The valid values are in a range of **0** to **500**. The default value is **5**. This option cannot be used with set_route_opt_strategy in Zroute mode.

-route_drc_threshold threshold
 Specifies the number of the route violation threshold for the tool to use to decide that the design has too many violations. If the design has too many route violations, the tool spends too much time on the search and repair stage. So, if the tool sees the design has too many violations, it optimizes the runtime for search and repair to reduce runtime impact due to route violation. If you specify **-1** for the *threshold* argument, the tool performs no checking and runs a full search and repair loop. The default value is **3000**.

-eco_route_search_repair_loops eco_routing_loop_count
 Specifies the number of search and repair loops in engineering change order (ECO) routing. If using zroute, it overrides the -max_number_iterations droute option during eco route. The default value is **5** for ICC router and **5** for Zroute.

DESCRIPTION

This command specifies the parameters that influence route_opt. The parameters are used for further tuning in route_opt and are design dependent. For detailed information on parameters, please see the user guide for the tool.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the detail routing search and repair loop to **20**.

```
prompt> set_route_opt_strategy -search_repair_loops 20
```

The following two examples both set the detail routing search and repair loop to **20** and the eco routing search and repair loop to **10**.

```
prompt> set_route_opt_strategy -search_repair_loops 20\
-eco_route_search_repair_loops effort 10
```

or

```
prompt> set_route_opt_strategy -eco_route_search_repair_loops 10
prompt> set_route_opt_strategy -search_repair_loops 20
```

ARGUMENTS

-default
 Set default options

-groute_timing_driven true | false
 Global route timing driven (default is false).

-groute_timing_driven_weight number
 Global route timing weight (default is 4). Range: 1 to 7.

-groute_skew_control true | false
 Global route skew control (default is false).

-groute_skew_weight number
 Global route skew weight (default is 5). Range: 0 to 10.

-groute_congestion_weight number
 Global route congestion weight (default is 4). Range: 1 to 12.

-groute_clock_routing normal | comb | balanced
 Global route clock topology (default is balanced).

-groute_incremental true | false
 Incremental global route (default is false).

-track_assign_timing_driven true | false
 TrackAssignment timing driven (default is false).

-track_assign_timing_driven_weight number
 trackAssignment timing weight (default is 1). Range: 1 to 10.

-droute_connect_tie_off true | false
 Detail route connect tie off (default is true).

-droute_connect_open_nets true | false
 Detail route connect open nets (default is true).

-droute_reroute_user_wires true | false
 Detail route reroute user wires (default is false)

-droute_CTS_nets normal | minor_change_only
 Detail route change CTS nets (default is minor_change_only).

-droute_single_row_column_via_array center | optimize
 Single row col via array (default is center).

```

-droute_stack_via_less_than_min_area forbid | add_metal_stub
    Stack via less than min area (default is add metal).

-droute_stack_via_less_than_min_area_cost number
    Add metal stub cost (default is 0). Range: 0 to 10.

-poly_pin_access auto | off
    Poly pin access (default is auto).

-drc_distance diagonal | manhattan
    drc distance (default is diagonal).

-same_net_notch ignore | check_and_fix
    Check same net notch (default is ignore).

-fat_wire_check quick | merge_then_check
    Check fat wire (default is merge_then_check).

-merge_fat_wire_on preroute_only | preroute_signal | preroute_signal_blockage
    Merge fat wire on (default is preroute_signal).

-fat_blockage_as thin_wire | fat_wire
    Treat fat blockages as (default is fat_wire).

-wire_contact_eol_rule ignore | check_and_fix
    Check end of line rule (default is ignore).

```

DESCRIPTION

This command does not actually invoke any routing. It only allows you to specify options that will be stored in a database for use by subsequent router steps.

Many of the options that can be set using the `set_route_options` command can also be set by `set_droute_options` commands.

Many of the options have a (true | false) syntax because it may be necessary to set the option true if it was originally set to false, or it may be necessary to set it to false if it was set previously to true.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> set_route_options -groute_clock_topology balanced
```

SEE ALSO

`set_droute_options(2)`
`route_detail(2)`

`set_route_options`
2632

set_route_type

Sets the route type of a group of objects.

SYNTAX

```
status set_route_type
[-signal detail_route | user]
[-clock ring | strap | tie_off | user]
[-pg ring | strap | tie_off | user | std_cell_pin_conn | macro/IO_pin_conn] objects
objects
```

ARGUMENTS

-signal detail_route | user
Sets the object type of signal wires/vias/paths as detail_route or user.

-clock ring | strap | tie_off | user
Sets the object type of clock wires/vias/paths as ring | strap | tie_off | user. The tie_off type is actually marked as detail_route.

-pg ring | strap | tie_off | user | std_cell_pin_conn | macro/IO_pin_conn
Sets the object type of power/ground wires/vias/paths as ring | strap | tie_off | user | std_cell_pin_conn | macro/IO_pin_conn. The tie_off type is actually marked as detail_route.

DESCRIPTION

This command allows you to set the route type of a group of objects. The objects must be provided with one of the options.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> set_route_type -signal detail_route\
[get_net_shapes -of_objects net_names]
```

SEE ALSO

`get_net_shapes(2)`

set_route_zrt_common_options

Sets the options common to all phases of routing.

Data Types

<i>int</i>	integer
<i>layer</i>	string
<i>multiplier</i>	float
<i>ratio</i>	float

ARGUMENTS

-child_process_net_threshold *int*
Specifies the minimum number of nets to trigger a separate router process. The default is -1, which means that the tool decides when to trigger a separate router process based on the number of nets in the design and the peak memory of the parent process when the routing command is run.

-concurrent_redundant_via_mode off | reserve_space | insert_at_high_cost
Specifies the concurrent redundant via mode for the initial routing. The valid modes are

- **off** (the default)
Concurrent redundant via optimization is turned off.
- **reserve_space**
Concurrent redundant via optimization reserves space for redundant vias but does not instantiate them. The space reservation is done by generating internal soft rules for redundant vias and performing soft-rule-based optimization. The actual instantiation can be done later by explicitly calling the **insert_zrt_redundant_vias** command or by setting the **-post_detail_route_redundant_via_insertion** common Zroute option.
- **insert_at_high_cost**
Concurrent redundant via optimization creates hard design rules for redundant vias and tries to optimize them. Use this mode if only you need a nearly 100 percent conversion rate. It can lead to very long runtimes if the design is congested or the technology parameters are not friendly to redundant via insertion. This mode should be used with caution.

-concurrent_redundant_via_effort_level low | medium | high
Specifies the effort level for the concurrent redundant via flow. The default value for effort level is low. The higher effort levels result in a better redundant via conversion rate at the expense of runtime. This option takes effect only if **-concurrent_redundant_via_mode** is set to a value other than **off**.

-eco_route_concurrent_redundant_via_mode off | reserve_space
Specifies the concurrent redundant via mode for ECO routing. The definition for each mode is

- **off** (the default)
Concurrent redundant via optimization is turned off.
- **reserve_space**
Concurrent redundant via optimization reserves space for redundant vias in ECO routing but does not instantiate them. The space reservation is done by generating internal soft rules for redundant vias and performing soft-rule-based optimization. The actual instantiation can be done later by explicitly calling the **insert_zrt_redundant_vias** command or by setting the **-post_detail_route_redundant_via_insertion** common Zroute option.

-eco_route_concurrent_redundant_via_effort_level low | medium | high
Specifies the effort level for the concurrent redundant via flow in ECO routing.

The default value for effort level is low. The higher effort levels result in a better redundant via conversion rate at the expense of runtime. This option takes effect only if **-eco_concurrent_redundant_via_mode** is set to a value other than **off**.

```
-connect_within_pins list of {layer off/via_standard_cell_pins/  
via_wire_standard_cell_pins/via_all_pins/via_wire_all_pins} pairs(off |  
via_wire_standard_cell_pins | via_standard_cell_pins | via_wire_all_pins |  
via_all_pins)
```

Specifies, for each layer, whether to connect to pins by using vias or wires contained within the pin shapes.

The routing layers are specified as m[1-15], where m1 is the bottommost routing layer. m[1-15] are logical names that might not match the names in the technology file.

The valid mode values are

- **off** (default)

Connect by using wires or vias anywhere on the pins.

- **via_standard_cell_pins**

Connect to standard cell pins by using vias contained within the pin shapes.

- **via_wire_standard_cell_pins**

Connect to standard cell pins by using vias and wires contained within the pin shapes.

- **via_all_pins**

Connect to any pins by using vias contained within the pin shapes.

- **via_wire_all_pins**

Connect to any pin by using vias and wires contained within the pin shapes.

```
-enforce_voltage_areas off | strict | relaxed
```

Specifies the level of enforcement of voltage areas. The definition for each mode is

- **off**

Voltage area constraints are turned off for routing.

- **strict**

Uses strict voltage area constraints for routing.

- **relaxed** (default)

Uses relaxed voltage area constraints for routing.

```
-extra_nonpreferred_direction_wire_cost_multiplier {{layer multiplier}...}
```

Specifies the cost multiplier for routing in the nonpreferred direction.

The routing layers are specified as m[1-15], where m1 is the bottommost routing layer. m[1-15] are logical names that might not match the names in the technology file.

The multiplier value must be between 0.0 and 20.0. The default is 0.0.

```
-extra_preferred_direction_wire_cost_multiplier {{layer multiplier}...}
```

Specifies the cost multiplier for routing in the preferred direction.

The routing layers are specified as m[1-15], where m1 is the bottommost

routing layer. m[1-15] are logical names that might not match the names in the technology file.
 The multiplier value must be between 0.0 and 20.0. The default is 0.0.

-extra_via_cost_multiplier {{layer multiplier}...}
 Specifies the cost multiplier for vias.
 The routing layers are specified as m[1-15], where m1 is the bottommost routing layer. m[1-15] are logical names that might not match the names in the technology file.
 The multiplier value must be between 0.0 and 20.0. The default is 0.0.

-freeze_layer {{layer true | false}...}
 Controls whether routing layers are frozen to prevent them from changing during routing.
 The routing layers are specified as m[1-15], where m1 is the bottommost routing layer. m[1-15] are logical names that might not match the names in the technology file.
 When false (the default), the layer is not frozen.
 When true, the layer is frozen.

-freeze_via_to_frozen_layer true | false
 Controls the treatment of vias that touch a frozen layer on one side.
 When false (the default), vias adjacent to a frozen layer can be changed.
 When true, vias adjacent to a frozen layer are frozen (cannot be changed).

-mark_clock_nets_minor_change true | false
 Controls whether changes on clock tree nets are limited during routing.
 When true (the default), the router can make only limited changes to nets marked as clock tree nets in the database.
 When false, nets marked as clock tree nets in the database are routed normally.

-max_layer_mode soft | allow_pin_connection | hard
 Controls the application of maximum routing layer constraints. Note that the **-number_of_vias_over_max_layer** option can relax the maximum layer constraint as well, but only for vias.
 The definition for each mode is

- **hard** (default)
 No routing can occur above the maximum layer.
- **soft**
 Routing above the maximum layer is discouraged, but not disallowed.
- **allow_pin_connection**
 Routing is allowed above the maximum layer only for pin connections.

-max_number_of_threads int
 Specifies the maximum number of concurrent threads the router can use. The actual number of threads used might be less than this number if a sufficient number of license keys is not available at the time the routing command is run.
 The default is 1.

```
-min_layer_mode soft | allow_pin_connection | hard
    Controls the application of minimum routing layer constraints. Note that the
    -number_of_vias_under_min_layer option can relax the minimum layer
    constraint as well, but only for vias.
    The definition for each mode is
```

- **soft** (default)

Routing below the minimum layer is discouraged, but not disallowed.

- **hard**

No routing can occur below the minimum layer.

- **allow_pin_connection**

Routing is allowed below the minimum layer only for pin connections.

```
-number_of_vias_over_max_layer int
```

Allows the router to use stacked vias to access pins or fixed routes above the maximum layer. If the maximum layer mode is set to **soft**, this option is ignored, because in that case access above the maximum layer is allowed. The value range is between 0 and 15.

The default is 1.

```
-number_of_vias_under_min_layer int
```

Allows the router to use stacked vias to access pins or fixed routes below the minimum layer. If the minimum layer mode is set to **soft**, this option is ignored, because in that case access below the minimum layer is allowed. The value range is between 0 and 15.

The default is 1.

```
-off_grid_routing_mode allow_off_grid | allow_end_points_off_grid | no_off_grid
```

Restricts routing use of off-routing-track wires.

The definition for each mode is

- **allow_off_grid** (default)

Routing can be off the routing tracks.

- **allow_end_points_off_grid**

The router routes most of the vias on grid points and most of the wires on track. The end points of wires can be off track.

- **no_off_grid**

The router routes most of the wires, including end points and vias, on track. You can also restrict off-grid routing by setting the onGrid attribute in the Layer section in the technology file.

The router does on-grid routing if either the **-off_grid_routing_mode** option or the onGrid attribute are set to enforce on-grid routing.

```
-plan_group_aware off | all_routing | top_level_routing_only
```

Specifies whether the plan group constraints are obeyed.

The definition for each mode is

- **off** (the default)

The router ignores plan groups and routes the design flat.

- **all_routing**

The router routes all nets and preserves the hierarchy and pin constraints for the pin cutting flow.

- **top_level_routing_only**

The router preserves the hierarchy and pin constraints, but it ignores intraplan group nets and routes only those nets that have top-level connections. This mode saves CPU time, but might be less accurate because it ignores the congestion due to intraplan group nets.

When you specify a mode other than **off**, the router gives priority to clock net routing. During floorplanning you might want to route the clocks flat to generate clock pins on the module boundaries. You should buffer these clocks later in the flow. The clock nets are routed before any other nets so that their pin placement has priority over normal signal pins.

-post_detail_route_redundant_via_insertion off | low | medium | high

Enables automatic redundant via insertion after each detail routing step. The default setting is off.

If the value is set to low, medium, or high, the tool performs redundant via insertion after each detail routing change, including initial detail routing, ECO routing, and incremental routing. Enabling this option keeps the redundant vias in the design up-to-date with routing changes. The low, medium, or high setting specifies the effort level used for redundant via insertion.

-read_user_metal_blockage_layer true | false

Specifies whether shapes on metal blockage layers should be honored (true) or ignored (false).

The default is false.

-reroute_clock_shapes true | false

Specifies whether the router can reroute fixed clock wires and vias. The default is false.

-reroute_user_shapes true | false

Specifies whether the router can reroute user-created wires and vias. The default is false.

-rotate_default_vias true | false

Specifies if the router can rotate default vias. The default is true.

-route_soft_rule_effort_level off | min | low | medium | high

Specifies the effort level for rip up and reroute to fix soft rule design rule violations. Each soft rule also has an **-optimize_soft_rule_effort_level** setting. The minimum of the two settings is used for each soft rule. The definition for each effort level is

- **off**

Does not perform rip up and reroute passes to resolve soft rule design rule violations.

- **min**

Uses the smallest number of rip up and reroute passes to resolve soft rule design rule violations.

- **low**

Uses a small number of rip up and reroute passes to resolve soft rule design rule violations.

- **medium** (medium)

Uses a medium number of rip up and reroute passes to resolve soft rule design rule violations.

- **high**

Treats soft rule design rule violations the same as regular design rule violations during rip up and reroute.

-route_top_boundary_mode stay_half_min_space_inside | stay_inside | ignore

Controls the routing behavior near the top boundary.

The definition for each mode is

- **stay_half_min_space_inside**

The routing must be inside the boundary by half of the minimum spacing.

- **stay_inside** (the default)

The routing must be inside (or abut) the boundary.

- **ignore**

Wires can extend outside the boundary.

-single_connection_to_pins off | standard_cell_pins | all_pins

Specifies whether the router can connect to a pin only once.

Valid values are

- **off** (the default)

Connect to any pin any number of times.

- **standard_cell_pins**

Connect to standard cell pins only once.

- **all_pins**

Connect to any pin only once.

-standard_cell_blockage_as_thin true | false

Specifies whether to treat wide blockages in standard cells as thin wires.

The default is false.

-threshold_noise_ratio ratio

Specifies the noise threshold as a fraction of the operating voltage.

The value range is from 0 to 1.

The default is 0.35.

-track_auto_fill true | false

Specifies whether to fill empty space with routing tracks.

The default is true.

-verbose_level int

Sets the verbosity level for the routing log file.

The value range is from 0 to 1.

The default is 0.

set_route_zrt_common_options

2640

```

-via_array_mode off | swap | rotate | all
    Specifies the types of rotated via arrays that can be used during signal
    routing and redundant via insertion.
    The definition for each mode is

    • off
        Do not rotate or swap via arrays.

    • swap (the default)
        Use 1 x N and N x 1 via arrays as rotated equivalent vias.

    • rotate
        Rotate line via arrays instead of swapping row and column numbers.

    • all
        Use all four possible via arrays.

-wide_macro_pin_as_fat_wire true | false
    Specifies whether a wide macro pin or pad pin should have an implicit depth
    the same as its width.
    The default value is false.

-default true | false
    If true, this option resets all options to their default values.
    The default is false.

```

DESCRIPTION

The **set_route_zrt_common_options** command sets options that are common to global routing, track assignment, and detail routing.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the **-enforce_voltage_areas** option to off.

```
prompt> set_route_zrt_common_options -enforce_voltage_areas off
```

The following example sets the **-threshold_noise_ratio** option to 0.2.

```
prompt> set_route_zrt_common_options -threshold_noise_ratio 0.2
```

The following example sets the **-freeze_layer** option to true for m3 and m4.

```
prompt> set_route_zrt_common_options -freeze_layer {{m3 true} {m4 true}}
```

<i>urx</i>	float
<i>ury</i>	float

ARGUMENTS

-antenna true | false
Enables (true) or disables (false) antenna analysis.
The default is true.

-antenna_on_iteration num
Specifies the routing iteration at which antenna analysis and optimization is turned on.
The range is from 1 to 19 (routing iteration number starts from 0).
The default is 1.

-antenna_verbose_level num
Specifies the verbosity level to print extra information for antenna analysis and optimization.
The range is from 0 to 1.
The default is 1.

-check_antenna_on_pg true | false
Enables (true) or disables (false) analysis and optimization of antennas on power and ground nets.
The default is false.

-check_pin_min_area_min_length true | false
Enables (true) or disables (false) checking for minimum area and minimum length rules on pins.
The default is false.

-check_port_min_area_min_length true | false
Enables (true) or disables (false) checking for minimum area and minimum length rules on physical ports (terminals).
The default is true.

-elapsed_time_limit limit
Specifies the limit for elapsed wall-clock time in minutes.
The range is from -1 to MAX_INT.
The default is -1, which means no limit.

-default true | false
If true, this option resets all options to their default values.
The default is false.

set_route_zrt_detail_options

2644

```

-default_diode_protection real
    Specifies the diode protection value used for pins during antenna analysis
    if the value is not specified in the cell.
    The range is from 0.0 to 1,000,000.00
    The default is 0.0.

-default_gate_size real
    Specifies the gate size used for pins during antenna analysis if the gate
    size is not specified in the cell.
    The range is from 0.0 to 1,000,000.00
    The default is 0.0.

-default_port_external_antenna_area real
    Specifies the antenna area value used for ports (top-level pins) during
    antenna analysis if the antenna area is not specified in the cell.
    The range is from 0.0 to 1,000,000.00
    The default is 0.0.

-default_port_external_gate_size real
    Specifies the gate size used for ports (top-level pins) during antenna
    analysis if the gate size is not specified in the cell.
    The range is from 0.0 to 1,000,000.00
    The default is 0.0.

-diagonal_min_width true | false
    Specifies whether to use diagonal distance for minimum width violations.
    If true (the default), diagonal distance is used.
    If false, manhattan distance is used.

-diode_libcell_names lib_cells
    Specifies the diode library cells to use for antenna fixing.
    The default is an empty list, in which case diodes are detected automatically.

-eco_route_use_soft_spacing_for_timing_optimization true | false
    Enables (true) or disables (false) soft-rule-based timing optimization during
    ECO routing.
    This option works only if the -timing_driven option is set to true.
    The default is true.

-force_max_number_iterations true | false
    Controls whether the maximum number of iterations must be run when DRCs do
    not converge.
    The default is false.

-generate_extra_off_grid_pin_tracks true | false
    Specifies whether to generate extra off-grid routing tracks for pin
    connections.
    The default is false.

-generate_off_grid_feed_through_tracks off | low | medium | high
    Specifies the effort level used to generate extra off-grid routing tracks for
    feedthrough nets between blockages.
    The default is low.

-ignore_drc {{same_net_metal_space | same_net_enclosed_cut_space |
```

all_same_net_drc_for_frozen_net
 all_same_net_drc_for_frozen_net true | false}..." Controls whether the router ignores specific design rule constraints (DRCs). When a DRC is ignored, the router neither analyzes nor fixes those violations.
 The valid DRC keywords are

- **same_net_metal_space**
 Ignore all same net metal space violations.
- **same_net_enclosed_cut_space**
 Ignore same net enclosed cut space violations.
- **all_same_net_drc_for_frozen_net**
 Ignore all same net violations on frozen nets.
 The default is false for all DRC types, which means that none of them are ignored.

-ignore_var_spacing_to_blockage true | false
 Specifies whether variable routing rule spacing is ignored against blockages.
 The default is false.

-ignore_var_spacing_to_pg true | false
 Specifies whether variable routing rule spacing is ignored against power and ground nets.
 The default is false.

-insert_diodes_during_routing true | false
 Specifies whether the router can use diode insertion to fix antenna violations.
 The default is false.

-max_antenna_pin_count int
 Specifies the maximum number of pins on a net on which antenna checking is performed. If a net has more than the specified number of pins, antenna checking is skipped; otherwise, antenna checking is performed.
 The range is from -1 to 1,000,000.
 The default is -1 (which means no limit).

-merge_gates_for_antenna true | false
 Enables (true) or disables (false) merging gates for antenna analysis.
 The default is true.

-optimize_tie_off_effort_level off | low | high
 Specifies the effort level used to optimize wire length and via counts for tie-off nets.
 The valid values are

- **off**
 No extra effort to optimize wire length and via counts for tie offs.
- **low** (the default)
 Low effort to optimize wire length and via counts for tie offs.
- **high**
 High effort to optimize wire length and via counts for tie offs.

set_route_zrt_detail_options

2646

-optimize_wire_via_effort_level off | low | medium | high
Specifies the effort level used to optimize wire length and via counts.
The valid values are

- **off**

No extra effort to optimize wire length and via counts.

- **low** (the default)

Low effort to optimize wire length and via counts.

- **medium**

Medium effort to optimize wire length and via counts.

- **high**

High effort to optimize wire length and via counts.

-pin_taper_mode default_width | pin_width | off
Specifies the pin tapering mode.

The valid values are

- **default_width** (the default)

Variable rule connections to pins are tapered to the default rule width.

- **pin_width**

Variable rule connections to pins are tapered to the pin width.

- **off**

Pin tapering is off.

-port_antenna_mode float | jump | top_layer

Specifies how the ports (top-level pins) are treated for antenna consideration.

The valid values are

- **float** (the default)

Treat ports as floating wires.

- **jump**

Treat ports as connected to a huge antenna and break the antenna (requiring a jumper at the top metal layer).

- **top_layer**

All input pins can be connected to ports only through the highest routing layer of the net.

-save_after_iterations iter_list

Saves the intermediate cell after the specified iterations.

The default is an empty list.

-save_cell_prefix prefix

Specifies the prefix to be used in the saved cell name.

The default is "DR".

-reshield_rerouted_nets off | unshield | reshield

Specifies whether to automatically unshield or reshield rerouted shielded

nets during routing.
The valid values are

- **off** (the default)

Do not unshield or reshield rerouted shielded nets.

- **unshield**

Delete existing shielding that is associated with rerouted shielded nets and reconnect floating shielding if necessary.

- **reshield**

Unshield rerouted shielded nets, automatically reshield them, and reconnect floating shielding. If the router cannot reconnect the floating shielding, it removes it.

-reuse.filler.locations_for_diodes true | false

Specifies whether to reuse filler cell locations for inserting diodes.
The default is true.

-timing_driven true | false

Specifies whether timing-driven routing is enabled.
The default is false.

-top_layer_antenna_fix_threshold int

Specifies the threshold for fixing antenna violations on the top routing layer. Antenna violations on the top routing layer are fixed if they are within *int* * 0.1% away from the safe ratio.
The range is from -1 to 10.
The default is -1 (which means no limit).

-use_default_width_for_min_area_min_len_stub true | false

Specifies whether to use default width stubs to fix minimum area and minimum length violations.
When false (the default), stubs are the same width as the via surround. When true, stubs are the default width.

-use_wide_wire_to_input_pin true | false

Specifies whether pin tapering to input pins is disallowed.
The default is false.

-use_wide_wire_to_macro_pin true | false

Specifies whether pin tapering to macro pins is disallowed.
The default is false.

-use_wide_wire_to_output_pin true | false

Specifies whether pin tapering to output pins is disallowed.
The default is false.

-use_wide_wire_to_pad_pin same_as_macro_pin | true | false

Controls pin tapering to pad pins.
The valid values are

- **same_as_macro_pin** (the default)

Setting is taken from **-use_wide_wire_to_macro_pin**.

- **true**
Allow pin tapering to pad pins.
- **false**
Disallow pin tapering to pad pins.

-use_wide_wire_to_port same_as_macro_pin | true | false
Controls pin tapering to ports.
The valid values are

- **same_as_macro_pin** (the default)
Setting is taken from **-use_wide_wire_to_macro_pin**.
- **true**
Allow pin tapering to ports.
- **false**
Disallow pin tapering to ports.

-user_defined_partition {llx lly urx ury}
Specifies the coordinates in database units of a rectangular partition {llx lly urx ury} to be added for routing. In general, the detail router automatically generates partitions to fix the DRCs in the design. In some situations, it might not generate the right-sized partitions. For example, when fixing DRCs in a river routing (single layer) situation over a macro, it might need the partitions to be thin and long. In such situations, you can assist the router by adding the right-sized partitions.

-var_spacing_to_same_net true | false
Specifies if variable routing rule spacing is to be applied to shapes of the same net.
The default is false.

DESCRIPTION

The **set_route_zrt_detail_options** command sets the options for detail routing.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the **-elapsed_time_limit** option to 60 minutes.

```
prompt> set_route_zrt_detail_options -elapsed_time_limit 60
```

The following example sets the **-antenna** option to false.

```
prompt> set_route_zrt_detail_options -antenna false
```

The following example shows how you can use the **-ignore_drc** option to allow the router to ignore same net metal space violations but not same net enclosed cut space violations.

```
prompt> set_route_zrt_detail_options \
-ignore_drc {{same_net_metal_space true} \
{same_net_enclosed_cut_space false}}
```

The following example uses the **-macro_pin_antenna_mode** option to set the macro pin antenna mode to **jump**.

```
prompt> set_route_zrt_detail_options -macro_pin_antenna_mode jump
```

The following example adds a user defined partition for routing using the **-user_defined_partition** option.

```
prompt> set_route_zrt_detail_options \
-user_defined_partition {100 200 500 3000}
```

SEE ALSO

`route_opt(2)`
`route_zrt_auto(2)`
`route_zrt_detail(2)`

set_route_zrt_global_options

Sets the options for global routing.

SYNTAX

```
status set_route_zrt_global_options
[-clock_topology comb | normal]
[-comb_distance int]
[-comb_max_connections int]
[-congestion_map_only true | false]
[-crosstalk_driven true | false]
[-default true | false]
[-effort minimum | low | medium | high]
[-macro_boundary_track_utilization int]
[-macro_boundary_width int]
[-macro_corner_track_utilization int]
[-timing_driven true | false]
```

Data Types

int integer

ARGUMENTS

```
-clock_topology comb | normal
    Specifies the global-routing clock topology.
    comb:      Use comb routing for clock nets with mesh or trunk.
    normal:    Use normal routing for clock nets.
    The default value is normal.

-comb_distance int
    Specifies the number of global route cells (gcells) within which to connect
    clock pins to the clock mesh.
    The range is from 0 to 50.
    The default is 2.

-comb_max_connections int
    Specifies the maximum number of pins that can be connected to any clock strap.
    The range is from -1 to 50.
    The default is -1, which means no limit.

-congestion_map_only true | false
    If false (the default), create both glinks and a congestion map. If true,
    create the congestion map without creating glinks.

-crosstalk_driven true | false
    Enables (true) or disables (false) crosstalk-driven global routing.
    The default is false.

-default true | false
    If true, this option resets all options to their default values.
    The default is false.
```

```
-effort minimum | low | medium | high
    Specifies the global route effort.
    minimum: Very fast run time.
    low: Fast run time.
    medium: Medium run time.
    high: Slow run time, but better QoR.

    The default is medium.

-macro_boundary_track_utilization int
    Specifies the percentage of tracks to be used along macro boundaries.
    The range is from 0 to 100.
    The default is 100.

-macro_boundary_width int
    Specifies the width of the macro boundary in terms of global route cells.
    The range is from 0 to 10.
    The default is 1.

-macro_corner_track_utilization int
    Specifies the percentage of tracks to be used along macro corners.
    The range is from 0 to 100.
    The default is 100.

-timing_driven true | false
    Enables (true) or disables (false) timing-driven global routing.
    The default is false.
```

DESCRIPTION

The **set_route_zrt_global_options** command sets the options for global routing.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the **-timing_driven** option to true.

```
prompt> set_route_zrt_global_options -timing_driven true
```

The following example sets the **-clock_topology** option to comb.

```
prompt> set_route_zrt_global_options -clock_topology comb
```

SEE ALSO

`report_route_zrt_global_options(2)`

`set_route_zrt_global_options`

2652

set_route_zrt_track_options

Sets the options for track assignment.

SYNTAX

```
status set_route_zrt_track_options
[-crosstalk_driven true | false]
[-default true | false]
[-timing_driven true | false]
```

ARGUMENTS

-crosstalk_driven true | false
Enables (true) or disables (false) crosstalk-driven track assignment.
The default is false.

-default true | false
If true, this option resets all options to their default values.
The default is false.

-timing_driven true | false
Enables (true) or disables (false) timing-driven track assignment.
The default is false.

DESCRIPTION

The **set_route_zrt_track_options** command sets the options for track assignment.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the **-timing_driven** option to true.

```
prompt> set_route_zrt_track_options -timing_driven true
```

SEE ALSO

`report_route_zrt_track_options(2)`

set_row_type

Sets a specified row type attribute on the specified rows.

SYNTAX

```
status set_row_type
[-site site_name row_name_list]
-type row_type
```

Data Types

<i>site_name</i>	string
<i>row_name_list</i>	list
<i>row_type</i>	int

ARGUMENTS

-site *site_name*

Specifies the name of the site, the specified *row_type* is set on all rows with this name. This option and the *row_name_list* are mutually exclusive; use only one.

row_name_list

Specifies one or more valid rows on which to set the row type attribute. The specified row names must exist in the floorplan. This argument and the **-site** option are mutually exclusive; use only one.

DESCRIPTION

The **set_row_type** command sets a row type attribute on a specified list of rows or on the rows of the specified site.

When you want to associate all the rows in a site to a particular *row_type*, use the **-site** option.

A row can only have one row type attribute.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to set a row type of 1 on the specified rows.

```
prompt>set_row_type -type_id 1 {ROW_0 ROW_1 ROW_2 ROW_4}
```

The following example shows how to set a row type for all rows in a specified site.

```
prompt>set_row_type -type_id 1 -site CORE1
```

SEE ALSO

`set_cell_row_type(2)`

set_rp_group_options

Sets relative placement group attributes on the specified relative placement groups.

SYNTAX

```
collection set_rp_group_options
rp_groups
[-alignment bottom-left | bottom-pin | bottom-right]
[-pin_align_name pin_name]
[-utilization percentage]
[-ignore]
[-x_offset float]
[-y_offset float]
[-compress]
[-cts_option fixed_placement | size_only]
[-route_opt_option fixed_placement | in_place_size_only]
[-psynopt_option fixed_placement | size_only]
[-move_effort low | medium | high]
[-allow_keepout_over_tapcell false | true]
```

Data Types

<i>rp_groups</i>	list or collection
<i>pin_name</i>	string
<i>percentage</i>	float
<i>float</i>	percentage

ARGUMENTS

rp_groups
Specifies the relative placement groups for which you want to change the attributes. This is a required argument.

-alignment bottom-left | bottom-pin | bottom-right
Specifies the default alignment method to use when placing leaf cells and relative placement groups in the specified relative placement groups. If you do not specify this option, the tool uses bottom-left alignment.
You can override the default alignment method for a specific leaf cell or relative placement group when you add it to a relative placement group (by using the **add_to_rp_group** command).

-pin_align_name *pin_name*
Specifies the default alignment pin for the specified relative placement groups. During placement, the tool uses the alignment pin's location to align the cells within a column when you use the bottom-pin alignment type.
You can override the alignment pin for a specific leaf cell when you add the cell to the group (by using the **add_to_rp_group** command).

-utilization *percentage*
Specifies the utilization percentage to use for placement of the specified relative placement groups. Utilization is represented as a floating-point number between 0.0 (representing 0%) and 1.0 (the default, representing

100%).

-ignore
 Indicates that the tool is to ignore the specified relative placement groups during placement and not treat them as relative placement groups. Instead, the tool places all of the group's parts individually, as it would normally do when there is no relative placement.

-origin

-x_offset float
 Specifies a left coordinate (anchor) for the group, in microns, relative to the lower-left corner in the core area, for top level relative placement group. It is ignored for a sub-level relative placement group. Specifying only an x-offset allows a group to slide in the y-direction.

-y_offset float
 Specifies a lower coordinate (anchor) for the group, in microns, relative to the lower-left corner in the core area, for top level relative placement group. It is ignored for a sub-level relative placement group. Specifying only a y-offset allows a group to slide in the x-direction.

-compress
 Applies compression in the horizontal direction to a relative placement group during placement. Setting this option places each row of a relative placement group without any gaps between leaf cells, lower-level hierarchical relative placement groups, or keepouts. Column alignment is not maintained when you use **-compress**.
 If you use **-alignment bottom-right** or **-alignment bottom-pin** and specify **-compress**, the tool issues a warning that **-alignment** is observed and **-compress** is ignored.
 If both **-utilization** and **-compress** are specified, the utilization constraints are observed with gaps between leaf elements in a relative placement row. The **-compress** option does not propagate from a parent group to child groups.

-cts_option fixed_placement | size_only
 Specifies how to treat the cells in the relative placement group during clock tree synthesis and clock tree optimization.
 If you specify **fixed_placement**, the cells in the relative placement group are treated as fixed during **compile_clock_tree**, **optimize_clock_tree**, and **fbclock_opt** activity and cannot be sized or moved.
 If you specify **size_only**, the cells in the relative placement group can only be sized. This option applies to the **compile_clock_tree**, **optimize_clock_tree**, and **clock_opt** commands.
 This option applies only to top-level relative placement groups and is ignored for hierarchical relative placement groups. The top-level value is propagated to the hierarchical relative placement groups.

-route_opt_option fixed_placement | in_place_size_only
 Specifies how to treat the cells in the relative placement group during **route_opt** and **psynopt on_route**.
 If you specify **fixed_placement**, the cells in the relative placement group are treated as fixed during **route_opt** and **psynopt on_route** and cannot be sized or moved.
 If you specify **in_place_size_only**, sizing changes are constrained for minimal

engineering change order (ECO) placement changes. For example, a cell is sized to improve timing or design rule costs only if the newly-sized cell can fit into any available space adjacent to the original cell location. The resulting transformation is verified to ensure it is legal.

This option applies only to top-level relative placement groups and is ignored for hierarchical relative placement groups. The top-level value is propagated to the hierarchical relative placement groups.

-psynopt_option fixed_placement | size_only

Specifies how to treat the cells in the relative placement group during **psynopt** and **place_opt**.

If you specify **fixed_placement**, the cells in the relative placement group are treated as fixed during **psynopt** and cannot be sized or moved. This value is not recommended for **fbplace_opt**.

If you specify **size_only**, the cells in the relative placement group can only be sized.

This option applies only to top-level relative placement groups and is ignored for hierarchical relative placement groups. The top-level value is propagated to the hierarchical relative placement groups.

-move_effort low | medium | high

This option controls the extent to which a relative placement group can be moved from its initial location to preserve the relative placement without violating relative placement constraints. The size of the region searched for placement of a relative placement group is progressively reduced as you reduce the effort from high to medium to low.

Coarse placement estimates an initial location for every top-level relative placement group. If those groups are placed at the same locations returned by coarse placement, the relative placement groups might need to be broken, which would violate the relative placement constraints for those groups.

Specifying high effort allows the higher movement of a relative placement group from its initial location in search of a location compared to low and medium effort, to maintain the relative placement constraints and potentially avoid breaking the relative placement group. The tradeoff for maintaining the relative placement group is a potential loss of QoR, because the group is moved from the location initially determined by coarse placement.

Specifying low effort indicates that the relative placement group is placed as close as possible to the initial location returned by coarse placement. The tradeoff for maintaining the location is a higher potential for breaking the relative placement groups and violating the relative placement constraints for some relative placement groups.

-allow_keepout_over_tapcell false | true

Specifies that the hard keepout in the relative placement group should be overlapped with tap cells if needed. By default, the value is false.

-compression

DESCRIPTION

The **set_rp_group_options** command sets the attributes of the specified relative placement groups. The same attributes can be set during the creation of the relative placement groups by using the **create_rp_group** command. This command is supported only for designs that do not contain multiply-instantiated designs.

This command returns a collection containing the relative placement groups for which the attributes have changed. If attributes have not changed for any object, the empty string is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **set_rp_group_options** to change the attributes for a relative placement group.

```
prompt> set_rp_group_options grp_ripple -utilization 0.95 -ignore
{ripple::grp_ripple}
```

SEE ALSO

```

all_rp_groups(2)
create_rp_group(2)
get_rp_groups(2)
remove_from_rp_group(2)
remove_rp_groups(2)
report_rp_group_options(2)
write_rp_groups(2)
```

set_scaling_lib_group

Specifies the scaling_lib_group to use for the current design, or a subdesign.

SYNTAX

```
status set_scaling_lib_group
[-min min_group]
[-max max_group]
[-object_list objects]
[group]
```

Data Types

<i>min_group</i>	string
<i>max_group</i>	string
<i>objects</i>	list
<i>group</i>	string

ARGUMENTS

-min *min_group*

Specifies the scaling library group to use for minimum delay analysis. If you do not specify a scaling library group for minimum delay analysis, the maximum group is used. The **-min** option cannot be used without the **-max** option. If neither of these options are specified, the library group applies to both max and min delay analysis.

-max *max_group*

Specifies the scaling library group to use for maximum delay analysis. If this option is not specified, the scaling group will be used for both maximum and minimum delay analysis.

-object_list *objects*

Specifies the cells or top level ports on which to specify the scaling library group(s). If you do not use this option, the group(s) are specified for the top level design. This option accepts both leaf cells and hierarchical blocks.

group

Specifies the scaling library group to use for both maximum and minimum delay analysis.

DESCRIPTION

The **set_scaling_lib_group** command set a scaling library group on the design objects, such that the tool can do interpolation between libraries in this group for voltage and/or temperature. The user can set scaling library for max and/or min mode. It is possible to set multiple scaling lib groups on an object.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

```
prompt> define_scaling_lib_group -name g1 {0.9.db 1.1.db 1.3.db}
prompt> set_scaling_lib_group -object_list top/inv g1
```

SEE ALSO

`define_scaling_lib_group(2)`
`remove_scaling_lib_group(2)`
`create_scenario(2)`
`set_operating_conditions(2)`

set_scan_pin_type

Sets the scan-in or scan-out type for the specified pin.

SYNTAX

```
status set_scan_pin_type
-type in | out
-pin pin | -ref_pin physical_lib_pin
```

Data Types

<i>pin</i>	collection
<i>physical_lib_pin</i>	collection

ARGUMENTS

- type in | out
 - Sets the type to scan-in or scan-out.
- pin *pin*
 - Specifies a collection of one pin.
- ref_pin *physical_lib_pin*
 - Specifies a collection of one physical lib pin.

DESCRIPTION

This command sets the scan-in or scan-out type on a given pin prior to executing the **trace_scan_chain** command. Scan-in and scan-out types are required to trace through multi-input cells in the scan path that are not scan cells. The scan type is set on the pin of the reference library cell. You must set either a pin or a physical lib pin as input.

The command returns 1 on success and 0 on failure.

You can specify the type as **in** or **out** for scan-in and scan-out, respectively.

To check the scan type of a pin, you can use the **is_scan_in** and **is_scan_out** attributes for scan-in and scan-out, respectively.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the *I* pin of the *buffd1* buffer in the *cb18os120.mw* library to have scan-in type.

```
prompt> set_scan_pin_type -type in -ref_pin\  
[get_physical_lib_pins cb18os120.mw/buffd1/I]
```

The following example sets the *I* pin of the *timer/buffd1* buffer to have scan-in type and uses the **get_attribute** command to see if the type is set.

```
prompt> set_scan_pin_type -type in -pin [get_pins timer/buffd1/I]  
1  
prompt> get_attribute [get_pins timer/buffd1/I] is_scan_in  
true
```

SEE ALSO

`get_attribute(2)`
`get_physical_lib_pins(2)`
`get_pins(2)`
`remove_scan_pin_type(2)`
`trace_scan_chain(2)`

set_scenario_options

Sets the scenario options for one or more scenarios.

SYNTAX

```
status set_scenario_options
[-scenarios scenario_list]
[-leakage_only true | false]
[-hold_only true | false]
[-setup true | false]
[-hold true | false]
[-leakage_power true | false]
[-dynamic_power true | false]
[-reset_all true | false]
```

Data Types

scenario_list list

ARGUMENTS

-scenarios *scenario_list*

Specifies the list of scenarios to apply the scenario options. When this option is not specified the command applies the scenario options to the current scenario.

-leakage_only true | false

When set to true, specifies that the scenario is designated only for leakage power cost. All other constraints from the scenario are ignored and their costs considered as 0 (zero). Default value of this option is false. This option can be applied only to active scenarios.

-hold_only true | false

When set to true, specifies that the setup cost and DRC checking are turned off for the scenario. But the leakage power cost is considered. Default value of this option is false. This option can be applied only to active scenarios.

-setup true | false

When set to true, enables setup(max delay) cost for the scenario; disables when set to false. When set to false, optimization ignores setup(max_delay) violation in the scenario. Default value of this option is true.

-hold true | false

When set to true, enables hold(min delay) cost for the scenario; disables when false. When set to false, optimization ignores hold(min_delay) violation in the scenario. Default value of this option is true.

-leakage_power true | false

When set to true, enables leakage power cost for the scenario; disables when false. Default value of this option is true.

```
-dynamic_power true | false
    When set to true, enables dynamic power cost for the scenario; disables when
    false. Default value of this option is true. When you set this option to true,
    you must also set the -setup option to true, for dynamic power calculation.
```

```
-reset_all true | false
    When set to true, resets all scenario options to default values. When set to
    false, the scenario options remain unchanged.
```

DESCRIPTION

This command sets options to restrict a scenario to be used for specific costs. Combinations of **-setup**, **-hold**, **-leakage_power**, and **-dynamic_power** can be used to restrict a scenario. The **-leakage_only** option sets the scenario for leakage power, but not for minimum or maximum delays and DRCs. The **-hold_only** option disables the scenario for max delays and DRCs. All scenario options, except the **-leakage_only** and **-hold_only**, can be applied to active and inactive scenarios. The **report_scenario_options** command can be used to report the options set by this command. The **report_scenarios** command can be used to see the current settings for **-leakage_only** and **-hold_only** options for all active scenarios.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example uses **set_scenario_options** command to set the MODE1 scenario as a leakage_only scenario that will be used only for leakage power in the multicorner-multimode flow:

```
prompt> create_scenario MODE1
Warning: Discarding all scenario specific information previously defined in this
session. (UID-1008)
Current scenario is: MODE1
1

prompt> set_scenario_options -leakage_only true
1

prompt> report_scenarios

`report_scenarios(2)`
`set_fix_hold(2)`
`set_max_leakage_power(2)`

set_scope

Specifies the current UPF scope. This command is supported only in UPF mode.

SYNTAX

```
string set_scope
[instance]
```

Data Types

instance string

ARGUMENTS

instance

Specifies the working instance in dc_shell.

- If *instance* is not specified, the focus returns to the top level of the current design.
- If *instance* is ".", the tool returns to the working instance.
- If *instance* is "..", the context is moved up one level in the hierarchy of the current design.
- If *instance* begins with "/", the tool returns to the working instance of the design whose name is after the "/".
- Multiple levels of hierarchy can be traversed in a single call to the **set_scope** command, by separating the cell names with a slash (/). More complex examples of *instance* arguments are described in the EXAMPLES section below.

DESCRIPTION

The **set_scope** command sets the current UPF scope. Functionally, this command is a subset of the **current_instance** command, but has a different return value. Upon success, the **set_scope** command returns the current UPF scope prior to the execution of this command as a full path string relative to the current design. The command returns a null string upon failure.

The **set_scope** command does not work on leaf cells. If you attempt to run the **set_scope** command on a leaf cell, the tool issues the following error message:

```
Error: A leaf cell instance A/B/leaf has been specified as the scope. (UPF-012)
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the UPF scope to the U1/U2 hierarchy, if the U1 cell exists in the current hierarchy and the U2 cell exists in the U1 cell.

```
prompt> set_scope U1/U2
```

The following example sets the scope to two levels of hierarchy above the current instance, and then down one level to the MY_INST cell.

```
prompt> set_scope ../../MY_INST
```

SEE ALSO

`current_design(2)`

set_separate_process_options

Sets options controlling whether IC Compiler uses separate OS processes for extraction, placement and routing.

SYNTAX

```
status set_separate_process_options
[-extraction true | false]
[-placement true | false]
[-routing true | false]
```

ARGUMENTS

-extraction true | false

Specifies, whether extraction should use a separate OS process or not. If true, a separate OS process is used. If false, extraction is run within the parent OS process.

-placement true | false

Specifies, whether placement should use a separate OS process or not. If true, a separate OS process is used. If false, placement is run within the parent OS process.

-routing true | false

Specifies, whether routing should use a separate OS process or not. If true, a separate OS process is used. If false, routing is run within the parent OS process.

DESCRIPTION

The **set_separate_process_options** command sets options controlling whether IC Compiler uses separate OS processes for extraction, placement and routing.

EXAMPLES

The following example sets the **-routing** process option to off.

```
prompt> set_separate_process_option -routing false
```

set_si_options

Defines signal integrity options used for analysis or optimization.

SYNTAX

```
status set_si_options
[-delta_delay true | false]
[-static_noise true | false]
[-timing_window true | false]
[-min_delta_delay true | false]
[-static_noise_threshold_above_low threshold_value]
[-static_noise_threshold_below_high threshold_value]
[-route_xtalk_prevention true | false]
[-route_xtalk_prevention_threshold threshold_value]
[-analysis_effort low | medium]
[-max_transition_mode normal_slew | total_slew]
[-reselect true | false]
```

Data Types

threshold_value float

ARGUMENTS

```
-delta_delay true | false
    Specifies whether crosstalk delta delay is considered in timing and
    optimization. When set to false, crosstalk delta delay is not considered.
    This option is disabled by default

-static_noise true | false
    Specifies whether static noise is considered in optimization. When set to
    false, static noise is not considered. This option is disabled by default

-timing_window true | false
    Specifies whether timing window overlapping is considered in crosstalk
    analysis. When set to true, timing window is considered. This option is
    disabled by default and can only be enabled when -delta_delay (or -
    static_noise) option is set to "true".

-min_delta_delay true | false
    Specifies whether min delta delay is considered in timing and optimization.
    When set to true, min delta delay enables crosstalk calculation for min timing
    paths reporting hold. This option also enables min noise propagation for
    capture clocks in max paths for setup, thereby speeding up the capture clock
    timing. This option is disabled by default and can only be enabled when -
    delta_delay is set to "true".

-static_noise_threshold_above_low threshold_value
    Specifies above low static noise threshold, measured in relative units, as
    the portion of Vdd. The actual absolute constraint used is obtained as the
    product of this threshold and Vdd.
```

```

-static_noise_threshold_below_high threshold_value
    Specifies below high static noise threshold, measured in relative units, as
    the portion of Vdd. The actual absolute constraint used is obtained as the
    product of this threshold and Vdd.

-route_xtalk_prevention true | false
    Specifies track assign xtalk prevention. This option is disabled by default.

-route_xtalk_prevention_threshold threshold_value
    Specifies the threshold during track assign xtalk prevention, measured in
    relative units, as the portion of Vdd.

-analysis_effort low | medium
    Specifies the effort level of the xtalk or noise analysis. The low effort
    runs faster than the medium effort. For better accuracy, the medium effort
    should be used. The default is low effort.

-max_transition_mode normal_slew | total_slew
    Specifies whether delta slew is included when estimating max transition
    violations.
    If total_slew is selected, the delta slew is added in maximum transition
    violation computations. If normal_slew is selected, the delta slew is not
    added.
    The default is normal_slew.

-reselect true | false
    Specifies whether net reselection is enabled in timing window overlapping
    analysis. This option is only effective when '-timing_window' option is true.

```

DESCRIPTION

The **set_si_options** command defines signal integrity options used for analysis or optimization.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all annotated delays, specifies crosstalk delta delay and static noise calculation and defines the threshold.

```
prompt> set_si_options -delta_delay true -static_noise true -
static_noise_threshold_below_high 0.3
```

SEE ALSO

`report_timing(2)`
`report_si_options(2)`

set_size_only

Sets a list of attributes on specified leaf cells so that they can be sized only in optimization during compile.

SYNTAX

```
int set_size_only
[-all_instances]
object_list
flag
```

Data Types

object_list	list
flag	Boolean

ARGUMENTS

-all_instances
Specifies that a cell in the object_list is an instance whose parent cell is not unique. All similar instance leaf cells under the parent design will automatically acquire the **size_only** attribute. This is especially useful for XG mode, since the *current design* does not have to be changed in order to issue this command in different designs.

object_list
Specifies a list of leaf cell instances on which the attributes is to be set.

flag
Determines the value to which the **size_only** attributes are to be set. The valid values are **true** or **false**. When you enter **set_size_only U1**, it is the same as entering **set_size_only U1 true**. By default, **true** is assumed.

DESCRIPTION

This command places the attributes **local_optz_off**, **const_prop_off**, **del_unloaded_gate_off**, and **resyn_off** on the specified cells, and sets their values to **true** or **false**. Setting the value to **true** allows only sizing optimizations to be performed on these cells during compile. A combination of these four attributes decides whether a particular cell is size only or not. Setting the value to **false** resets it to its default value.

To remove the **size_only** attributes, set **size_only** to **false**.

When the **set_size_only** command is issued with the **true** value on a cell, optimization of that part is treated specially. In general, this command directs synthesis to perform only a sizing operation on a cell. The **set_size_only** command can be used only on leaf cell instances.

NOTE: The **false** value on the **local_optz_off**, **const_prop_off**, **del_unloaded_gate_off**, and **resyn_off** attributes could be overridden by the tool implied **size_only** attribute

when necessary. Use the **report_cell** command to see if the cell is size only, only or not.

For example, if you flag a cell instance as **size_only**, the **compile** command attempts to optimize this cell by replacing it with a cell of the same function.

Setting **size_only** on a cell does not prevent changes to the net driven by this cell. For example buffers may be added to this net. To prevent changes to the net, it should be marked **dont_touch** using **set_dont_touch** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the attributes **local_optz_off**, **const_prop_off**, **del_unloaded_gate_off**, and **resyn_off** to **true** on a cell named *U1*.

```
prompt> set_size_only U1
```

The following example sets the attributes **local_optz_off**, **const_prop_off**, **del_unloaded_gate_off**, and **resyn_off** to **false** on a cell named *U1*.

```
prompt> set_size_only U1 false
```

The following example uses the **-all_instances** option.

```
prompt> set_size_only -all_instances mid1/bot1/c1
Information: Set size_only for all instances of cell 'c1'
in subdesign 'bot'. (UID-193)
1
```

SEE ALSO

```
get_attribute(2)
report_attribute(2)
report_cell(2)
```

set_skew_group

Creates a new user-defined skew group.

SYNTAX

```
set_skew_group
[-name ]
[-target_skew desired_skew]
[-target_early_delay minimum_insertion_delay]
list_of_sink_pin or net_name
```

Data Types

<i>desired_skew</i>	float
<i>minimum_insertion_delay</i>	float

ARGUMENTS

DESCRIPTION

This command creates a user-defined skew group. Sink pins specified in a skew group will be balanced against each other to meet the specified desired skew and target early delay.

Incremental addition of sink pins in a skew group definition is not supported.

EXAMPLES

The following example creates a skew group named grp1 with reg_g2/D1/CK and reg_g2/D2/CK as sink pins:

```
prompt> set_skew_group -name grp1 {reg_g2/D1/CK reg_g2/D2/CK}
```

SEE ALSO

```
report_skew_group(2)
remove_skew_group(2)
```

set_spacing_label_rule

Sets intercell spacing constraint between reference cells that have been assigned labels with set_lib_cell_spacing_label command.

SYNTAX

```
status set_spacing_label_rule
-labeled {list_of_label_names}
{min max}
```

Data Types

list_of_label_names list of strings

ARGUMENTS

```
-labeled {list_of_label_names}
          Lists inter-cell constraint labels. The list must contain exactly two labels
          previously specified by the set_lib_cell_spacing_label command.

{min max}
          Specifies illegal spacing range given in units of sites, where max >= min.
```

DESCRIPTION

This command assigns inter-cell spacing constraints between reference cells that have been assigned labels with the set_lib_cell_spacing_command. Cells with the given labels are prohibited from being placed adjacent to one another within the range given by min and max. The range is specified in units of placement sites. Given two adjacent standard cells with an empty space in between, each label from the right side of the left cell is checked against each label from the left side of the right cell to see if any spacing rules are violated. Such pair wise checking of labels is applied to all adjacent cells to ensure placement legality of a chip.

A label typically represents some layout features inside a standard cell. A label is associated with the left or right boundary of a standard cell in the North orientation when specified. When a cell is flipped, its associated labels will also be flipped.

All spacing rules specified by set_spacing_label_rule commands need to be satisfied to produce a legal placement. With inter-cell spacing rule specified, it is no longer assumed that any two standard cells can be placed next to each other with a certain spacing.

The labels and spacing rules can be used to express spacing requirements that originate from mask rules and the layout of standard cells. The labels and spacing rules are stored in the library and will be applied to all designs of the library once specified.

Built-in label 'SNPS_BOUNDARY' may be used to specify spacing rules between library cells and various types of placement boundaries: chip boundary, hard macro edge,

hard macro keepout margin, hard placement blockage edge, or voltage area guard bands.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, cells with labels "X" and "Y" are prohibited to abut (illegal spacing of 0).

```
prompt> set_spacing_label_rule -labels {X Y} {0 0}
```

In the following example, cells with labels "X" are prohibited to be spaced within range of 3 to 5 placement sites.

```
prompt> set_spacing_label_rule -labels {X X} {3 5}
```

In the following example, cells with labels "X" are prohibited to be spaced within range 0 to 1 placement sites from placement boundary.

```
prompt> set_spacing_label_rule -labels {X SNPS_BOUNDARY} {0 1}
```

SEE ALSO

```
set_lib_cell_spacing_label(2)  
report_spacing_rules(2)  
remove_all_spacing_rules(2)
```

set_split_clock_gates_options

Set options for the **split_clock_gates** command.

SYNTAX

```
status set_split_clock_gates_options
[-slack_margin margin_value]
[-honor_dont_touch]
[-honor_size_only]
```

ARGUMENTS

-slack_margin *margin_value*

Specifies the timing margin for timing slack. When the timing slack on the enable pin of an integrated clock-gating (ICG) cell is less than the specified nonzero value, it is seen as a timing violation. By default, if the timing slack on the enable pin is a positive value or zero, the ICG will not be replicated (split).

-honor_dont_touch

By default, **split_clock_gates** can replicate ICGs that have the **dont_touch** attribute. When you set this option, such ICGs will not be replicated.

-honor_size_only

By default, **split_clock_gates** can replicate ICGs that have the **size_only** attribute. When you set this option, such ICGs will not be replicated.

DESCRIPTION

This command sets the options for **split_clock_gates**.

EXAMPLES

The following example shows that **split_clock_gates** will replicate any clock gates with a negative slack of 0.05 or worse if the clock gates drive buffer trees.

```
prompt> set_split_clock_gates_options -slack_margin -0.05
prompt> split_clock_gates
```

SEE ALSO

```
split_clock_gates(2)
reset_split_clock_gates_options(2)
report_split_clock_gates_options(2)
```

set_starrcxt_options

Sets up StarRCXT options for the **signoff_opt** command.

SYNTAX

```
status set_starrcxt_options
[-default]
[-exec_dir string]
[-max_nxtgrd_file string]
[-min_nxtgrd_file string]
[-map_file string]
[-num_parts integer]
[-mode 100 | 150 | 200 | 400]
[-option_file string]
[-min_image string]
[-max_image string]
```

ARGUMENTS

```
[-default]
    Resets all options to the default.

[-exec_dir string]
    Specifies the UNIX path to the StarRCXT executable StarXtract. The path can
    be either relative or complete.

[-max_nxtgrd_file string]
    Specifies the StarRCXT technology file (nxtgrd) for max corner extraction.

[-min_nxtgrd_file string]
    Specifies the StarRCXT technology file (nxtgrd) for min corner extraction.
    This argument is optional.

[-map_file string]
    Specifies the StarRCXT layer mapping file.

[-num_parts integer]
    Specifies the number of partitions to run StarRCXT with distributed
    processing capability. The default is NOT to use StarRCXT's distributed
    processing capability.

[-mode 100 | 150 | 200 | 400]
    Specifies the extraction mode used by StarRCXT. Default is 200.

[-option_file string]
    Specifies an option file that is used by StarRCXT. The option file contains
    a list of options that are used in the command file.

[-max_image string]

[-min_image string]
    Specifies the run directory from a previous StarRCXT run. The signoff_opt
```

command loads the run directory as max/min corner, and continues optimization. Because **StarRCXT** was run standalone, you must maintain the netlist consistency between the **StarRCXT** run and **IC Compiler**. An inconsistent netlist, for example, StarRCXT's netlist has one more buffer than IC Compiler, can lead to unexpected results when running **signoff_opt**.

DESCRIPTION

The **set_starrcxt_options** command sets up StarRCXT options for **signoff_opt**. Use **report_starrcxt_options** command to examine the options.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **set_starrcxt_options** command.

```
prompt> open_mw_cel -lib my_lib my_cel
prompt> set_starrcxt_options -exec_dir /StarRCXT/linux/bin
      -max_nxtgrd_file /design/max.nxtgrd -map_file /design/map_file
prompt> save_mw_cel
```

SEE ALSO

signoff_opt(2)
place_opt(2)
clock_opt(2)
route_opt(2)

set_switching_activity

Sets switching activity annotation on nets, pins, ports and cells of the current design.

SYNTAX

```
int set_switching_activity
[-static_probability sp_value]
[-toggle_rate tr_value]
[-state_dep state_condition]
[-path_dep path_sources]
[-rise_ratio ratio_value]
[-period period_value | -clock clock_name]
[-select select_types]
[-hier]
[-instances instances]
[object_list]
[-verbose]
```

Data Types

<i>sp_value</i>	float
<i>tr_value</i>	float
<i>state_condition</i>	string
<i>path_sources</i>	list
<i>ratio_value</i>	float
<i>period_value</i>	float
<i>clock_name</i>	string
<i>select_types</i>	list
<i>instances</i>	list
<i>object_list</i>	list

ARGUMENTS

-static_probability *sp_value*

Specifies the static probability value. The static probability is a floating point number between 0.0 and 1.0 and represents the percentage of the time the signal is at the logic state 1. For example, a static probability value of 0.25 indicates that the signal is in the logic state 1 for 25% of the time.

-toggle_rate *tr_value*

Specifies the toggle rate value. The toggle rate is a positive floating point number that represents the number of 0->1 and 1->0 transitions that the signal makes during a period of time. The period is by default 1 units and can be specified with the **-period** option. The time units used are the main library time units. Alternatively, a related clock can be annotated using the **-clock** argument, and the specified toggle rate will be relative to the related clock period.

-state_dep *state_condition*

Specifies the state condition when annotating state-dependent toggle rates on pins or state-dependent static probabilities on cells. State dependent

toggle rates can be annotated when the internal power of the library cell pin is characterised with state-dependent power tables. State-dependent static probabilities can be annotated when the cell leakage power is characterised with state-dependent power tables. The state condition specified with this argument must be logically equivalent to a state condition in the internal / leakage power characterization.

-path_dep *path_sources*

Specifies the path sources when annotating path-dependent toggle rates on pins. This can be used when the library cell pin has path-dependent internal power characterization. The path source(s) specified with this argument must be the same as those in the internal power characterization.

-rise_ratio *ratio_value*

Specifies the ratio of rise transitions to total transitions for the specified toggle rate when annotating pins that are characterised with both rise and fall internal power. The *ratio_value* argument is a floating point number between 0.0 (all transitions are falling) and 1.0 (all transitions are rising). You need to specify a toggle rate in order to use this option. The default value is 0.5.

-period *period_value*

Specifies the time period for which the number of transitions given in the toggle rate *tr_value* occur; The time units for this value are those specified in the main technology library. When this argument is used, the *tr_value* specified by the **-toggle_rate** argument is divided by the given *period_value*; The resulting toggle rate is then annotated to the object(s) given to the **set_switching_activity** command. If the **-period** argument is not specified, a default *period_value* of 1.0 is assumed.

-clock *clock_name*

Specifies a clock to which *tr_value* is related. This clock is referred to as the object's related clock. When specified, the related clock is annotated to the design object(s), and during power calculations the annotated toggle rate value is divided by the related clock period. The resulting toggle rate is then used for calculating power. The clock period can be changed between different runs of **report_power** and the resulting change in the toggle rate of the design objects will be used automatically without re-annotating the switching activity. The user can also specify "*" as the *clock_name* value of the **-clock** argument. This specifies that Power Compiler will infer the related clock on the design object automatically before power calculations. The mechanism used to infer related clocks is described in the man page of **propagate_switching_activity**.

-select *select_types*

Specifies a list of object types that will be used for implicitly selecting the objects that will be annotated with the specified switching activity information. The *select_types* argument can be a list of one or more of the following object types: **regs** (sequential cell outputs), **tris** (tristate cell outputs), **black_boxes** (black box cell outputs), **inputs** (input design ports / hierarchical instance pins), **outputs** (output design ports / hierarchical instance pins), **inout** (inout design ports / hierarchical instance pins), **ports** (design port / hierarchical instance pins), **nets** (nets), **regs_on_clocks** *clock_list* (outputs of flip-flops clocked by the clocks in *clock_list*). When the **-select** argument is used all the objects in the current instance (current

design, if no current instance is set) that satisfy the selection criteria will be annotated with the specified switching activity. If the **regs** or **regs_on_clocks** selection type is used, both the non-inverting (Q) and inverting (QN) sequential cell outputs are annotated. The non-inverting outputs are annotated with the specified toggle rate and static probability. The inverting outputs are annotated with the specified toggle rate. The annotated static probability on the inverting outputs is $1.0 - sp_val$ where sp_val is the specified static probability. The **regs_on_clocks** selection type needs the argument *clock_list* which is a list of clock names. This selection type selects all the registers that are clocked by a clock whose name is in *clock_list*. A register is clocked by a clock *clk* if the clock pin of the register is in the transitive fanout of the source port/pin of the clock *clk*. The **regs_on_clock** selection type can only be used in XG mode. Note that although the **regs** selection type applies to both flip-flops and latches, the **regs_on_clock** selection type applies only to flip-flops. Both the **regs** and **regs_on_clocks** selection types exclude clock-gating logic cells, which may have internal latches and are therefore sequential cells.

Note that the *object_list* argument for explicity specifying the objects to be annotated, and the **-select** argument for implicity specifying the objects to be annotated, are mutually exclusive.

-hier

Used with the **-select** argument and specifies that all the objects in all the hierarchy that satisfy the selection criteria will be annotated. If not specified only the top level objects in the current instance will be considered.

-instances instances

Used with the **-select** argument and specifies that all the objects in the given list of instances that satisfy the selection criteria will be annotated. This option can also be used with the **-hier** option.

object_list

Specifies a list of nets, pins, ports or cells in the current design on which the **static_probability** and **toggle_rate** switching activity values are to be set.

Note that the *object_list* argument for explicity specifying the objects to be annotated, and the **-select** argument for implicity specifying the objects to be annotated, are mutually exclusive.

-verbose

Provides a more verbose output when switching activity is annotated.

DESCRIPTION

This command can be used to annotate design nets, ports, pins and cells with the different kinds of switching activity. These include simple toggle rate and static probability on nets, ports and pins; state and path dependent toggle rates on cell pins, and state dependent static probabilities on cells.

Toggle rates and static probabilities are annotated using the **-toggle_rate** and **-static_probability** arguments respectively. The toggle rate and static probability can be made state dependent by specifying the state condition with the **-state_dep** argument. The toggle rate can be made path dependent by specifying the path

source(s) with the **-path_dep** argument. A related clock can be specified using the **--clock** argument. The annotated toggle rate is divided by the related clock period during power calculation to calculate the effective toggle rate. When none of the **-toggle_rate**, **-static_probability** and **-clock** arguments are given, then annotated switching activity is removed from the specified objects.

The design objects that will be annotated with switching activity can be specified explicitly as a list of objects. The objects can also be specified implicitly by the **-select**, **-hier** and **-instance** arguments.

For statistics on the switching activity annotation on the current design use the **report_saif** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following **set_switching_activity** command annotates a simple toggle rate value of $33 / 1320 = 0.025$ and a static probability value of 0.015 to all design input ports.

```
prompt> set_switching_activity -toggle_rate 33 -period 1320 -  
static_probability 0.015 [get_inputs]
```

The following example annotates a toggle rate value of 0.25 and a static probability value of 0.015 to all design input ports. The clock CLK is specified as the related clock for all inputs.

```
prompt> create_clock CLK -period 10  
prompt> set_switching_activity -toggle_rate 0.25 -clock CLK -  
static_probability 0.015 -select inputs
```

When power is calculated, the annotated toggle rate value 0.25 is divided by the related clock period (10) and the resulting toggle rate (0.025) is used.

The following example annotates state dependent static probabilities on the cell or1:

```
prompt> set_switching_activity -static_probability 0.10 -state "A & B"  
[get_cell or1]  
prompt> set_switching_activity -static_probability 0.35 -state "A & ! B"  
[get_cell or1]  
prompt> set_switching_activity -static_probability 0.25 -state "! A & B"  
[get_cell or1]  
prompt> set_switching_activity -static_probability 0.30 -state "! A & ! B"  
[get_cell or1]
```

The following example annotates simple and path dependent toggle rates on the output pin Y of the cell xor1:

```
prompt> set_switching_activity -toggle_rate 0.022 [get_pin xor1/Y]  
prompt> set_switching_activity -toggle_rate 0.020 -path "A" [get_pin xor1/Y]
```

```
prompt> set_switching_activity -toggle_rate 0.002 -path "B" [get_pin xor1/Y]
```

The following example removes the switching annotation from all sequential cell outputs in the current design:

```
prompt> set_switching_activity -select regs -hier
```

The following example annotates switching activity on all the registers in the current design that are clocked by the clock clk1 or clk2.

```
prompt> set_switching_activity -toggle_rate 0.1 -static_probability 0.5 -  
select {regs_on_clock {clk1 clk2}} -hier
```

The following example annotates all primary inputs with a toggle rate of 0.2, a static probability of 0.5 and a related_clock attribute with value "*". When power is calculated during the **report_power** command, the related clocks on the design inputs are inferred automatically and the toggle rate value of 0.2 is scaled by the related clock period. The man page of the **propagate_switching_activity** command gives more details on the mechanism used to infer related clocks.

```
prompt> set_switching_activity -toggle_rate 0.2 -static_probability 0.5 -  
clock "*" -select inputs prompt> report_power
```

SEE ALSO

propagate_switching_activity(2)  
report_power(2)  
create_clock(2)
```

set_synlib_dont_get_license

Specifies a list of synthetic library part licenses that are not automatically checked out.

SYNTAX

```
int set_synlib_dont_get_license  
license_list
```

ARGUMENTS

license_list

Lists synthetic library part licenses that are not automatically checked out.

DESCRIPTION

Specifies a list of synthetic library part licenses that are not automatically checked out. By default, all synthetic library part licenses are automatically checked out if there is a possibility that they will be used. Add licenses to this list if they should not be automatically checked out when only the possibility of their use exists. The exception that licenses on this list may be checked out is, but only when read a design that **required** to have these licenses, or when manually requested via the **get_license** command. To determine what licenses are required for reading a design, use freport_design command.

If all licenses in the list present in the key file, the command sets synlib variable fsynlib_dont_get_license to be the same list of licenses. To determine the current value of fsynlib_dont_get_license, type **list synlib_dont_get_license**.

The **set_synlib_dont_get_license** command fails if any of the license key is mistyped in the command or not present in the key file.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example issues an error message because the license key is mistyped in the command or not present in the key file.

```
prompt> set_synlib_dont_get_license \  
      {"Synlib_advMath" "Synlib_ALU"}
```

Warning: Unrecognized key 'Synlib_advMath' found in 'synlib_set_dont_get_license' command. (UISN-30)

Warning: Unrecognized key 'Synlib_ALU' found in 'synlib_set_dont_get_license' command. (UISN-30) 0

The following example specifies that licenses named DesignWare-Foundation-Ultra and

SynLib-AdvMath are not to be automatically checked out.

```
prompt> set_synlib_dont_get_license \
           {DesignWare-Foundation-Ultra SynLib-AdvMath}
{ "DesignWare-Foundation-Ultra", "SynLib-AdvMath" }
1
```

SEE ALSO

`get_license(2)`
`report_design(2)`

set_target_library_subset

Restricts optimization of a block to use a given subset of the target_library, for cases where operating condition alone is not sufficient to define the subset.

SYNTAX

```
int set_target_library_subset
[-object_list cells]
[-top]
library_list
[-milkyway_reflibs milkyway_reflib_paths]
```

ARGUMENTS

-object_list *cells*

Specifies the cells on which to set the target library subset. The cells should be instances of hierarchical designs, and the subset restriction applies to those instances and their children. Target library subset does not apply onto leaf level cells. You must specify at least one from **-top** and **-object_list**. If neither **-top** nor **-object_list** is specified, nothing is applied.

-top

If specified, the target library subset is set on the root design. You must specify at least one from **-top** and **-object_list**. If neither **-top** nor **-object_list** is specified, nothing is applied.

library_list

The list of library filenames to use for optimization of the identified design instances. The list of libraries must be a subset of the libraries specified in \$target_library. This option is a required option.

-milkyway_reflibs *milkyway_reflib_paths*

Specifies a list of Milkyway reference library paths to associate with the provided instance objects. When specifying more than one reference library, enclose them in braces ({}). The library list specified here must be a subset of the designs reference library list. For DC, we don't do any checking on this option, DC just preserve this option through nid (mw database) and **write_script** command.

DESCRIPTION

Sets a subset of the target_library which may be used for optimization of the given instances. Normally, optimization will select any lib_cell which is suitable for the local operating conditions. This command is intended only for situations where operating conditions alone are not sufficient to define which lib_cells to use in optimization.

The library_list must be a subset of the libraries listed in \$target_library.

The subset applies to the identified instances, and their children. Another subset

at a lower level completely overrides any subset specified at a higher level.

The subset restriction only applies to new cells that are created or mapped during optimization. It does not affect any cells that are already mapped. This allows changes to be restricted without affecting the unchanged portions of the design.

To remove a target_library_subset from the design or a design instance, use **remove_target_library_subset** command or use **reset_design**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the target_library for the design to the full set of libraries "lib1.db lib2.db", but restricts the lib_cells used in block u1 to those in library lib2.db.

```
prompt> set target_library "lib1.db lib2.db" prompt>
set_target_library_subset "lib2.db" \ -object_list [get_cells u1]
```

SEE ALSO

[remove_target_library_subset\(2\)](#)
[report_target_library_subset\(2\)](#)
[check_target_library_subset\(2\)](#)
[set_operating_conditions\(2\)](#)
[target_library\(3\)](#)

set_timing_derate

Sets derate factors on the current design or specified objects. Derate factors specify upper and lower limits on delays for a particular operating condition.

SYNTAX

```
int set_timing_derate
[-min]
[-max]
[-early]
[-late]
[-clock]
[-data]
[-net_delay]
[-cell_delay]
[-cell_check]
value
object_list
```

Data Types

<i>value</i>	float
<i>object_list</i>	list

ARGUMENTS

-min

Specifies that the derate value is set for minimum operating condition. If neither the **-min** or **-max** option is specified, the derate value is applied to both operating conditions.

-max

Specifies that the derate value is set for maximum operating condition. If neither the **-min** or **-max** option is specified, the derate value is applied to both operating conditions.

-early

Specifies that the value is the minimum derate factor. This factor defines how early the signal could arrive. If neither the **-early** or **-late** option is specified, the derate value is applied to both.

-late

Specifies that the value is the maximum derate factor. This factor defines how late the signal could arrive. If neither the **-early** or **-late** option is specified, the derate value is applied to both.

-clock

Indicates that the derate value is to apply to elements on the clock network only. If neither the **-clock** or **-data** option is specified, the derate value is applied to both clock path and data path.

-data
Indicates that the derate value is to apply to elements on the data network only. If neither the **-clock** or **-data** option is specified, the derate value is applied to both clock path and data path.

-net_delay
Applies the derate value to net delay, which is the delay from the driver to the receiver of each net. This command cannot be used with an object list. There is only one set of derate values for net delays and they apply to the whole design.

-cell_delay
Applies the derate value to cell delay, which is the delay from the input to the output of a cell.

-cell_check
Applies the derate value to the setup and hold time requirements of cells: cell setup and cell recovery times for late derating or cell hold and cell removal times for early derating.

value
Specifies the derate value. It has to be in the range of 0.1 and 2.0.

object_list
Specifies a list of the names of leaf cells, instances or library cells for which the derate factor is to be set.

DESCRIPTION

The `set_timing_derate` command sets derate factors for the current design or specified objects. If timing derate factors are specified, some or all path delays are multiplied by derate factors. Derate factors define lower and upper ranges of timing for a certain operating condition. The derate factor specified with the **-late** option multiplies data paths delays for maximum delay (setup) check and clock paths delays for minimum delay (hold) check. The derate factor specified with the **-early** option multiplies data paths for hold checks and clock paths for setup checks.

The options **-net_delay**, **-cell_delay** and **-cell_check** apply the specified derate value to net delays, cell delays, or cell setup/hold time requirements, respectively. The **-net_delay** option can apply to the whole design only, so it cannot be used with an object list.

If none of these three options is used and an object list is provided, the derate value applies to cell delay only; or if no object list is provided, the value applies to both cell delay and net delay.

Setup timing check is calculated using maximum operating condition. Hold timing check is calculated using minimum operating condition.

Input delay and ideal clock network latency is not derated.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example specifies an early derate value of 0.9 and a late derate value of 1.1 for all clock network nets in maximum operating condition.

```
prompt> set_timing_derate -max -early -net_delay 0.9
prompt> set_timing_derate -max -late -net_delay 1.1
```

The next example specifies an early derate of 0.8 and a late derate value of 1.2 for leaf cell U1 for maximum operating condition.

```
prompt> set_timing_derate -max -early 0.8 U1
prompt> set_timing_derate -max -late 1.2 U1
```

SEE ALSO

`report_timing_derate(2)`
`report_timing(2)`

set_timing_ranges

Sets timing ranges for the current design.

SYNTAX

```
int set_timing_ranges
[timing_ranges]
[-library library_name]
```

Data Types

library_name string

ARGUMENTS

timing_ranges

One or two timing ranges to be applied to the current design.

-library library_name

Specifies the name of the library that contains definitions of the timing ranges used.

DESCRIPTION

Specifies the names of one or two timing ranges to be used for timing the current design. The specified timing ranges must be defined in *library_name*, or in one of the libraries in the **link_library**. If a **local_link_library** is set on the current design, it is prepended to (added to the beginning of) the **link_library** before the **link_library** is searched. That is, the order for a library search is:

1. *library_name*
2. **local_link_library**
3. **link_library**

Timing ranges define scaling factors that are used to scale timing path totals. You can model operating condition variations using timing ranges, by defining a range of relative slow and fast times.

The *slowest_factor* is the largest value of any of the specified timing ranges. The *fastest_factor* is the smallest value of any of the specified timing ranges. Maximum delays of data paths are scaled by the *slowest_factor*. Minimum delays of data paths are scaled by the *fastest_factor*. Timing ranges do not affect the clock network. The effect of this command can be seen with the **report_timing**, **report_constraint**, and **compile** commands. Timing ranges affect path delays for reports, such as **report_timing** and **report_constraints**, and affect delay cost computation during optimization.

The following is an example of a timing range definition, as it appears in the source text of a library:

```
timing_range("BEST_CASE") {     faster_factor : 0.95
```

```
        slower_factor : 0.99
    }
```

The name of this timing range is "BEST_CASE". The fields are defined as follows:

faster_factor

A floating-point number by which arrival times are scaled to model faster times due to environmental variations.

slower_factor

A floating-point number by which arrival times are scaled to model slower times due to environmental variations.

The **report_lib -timing_arcs** command shows the timing ranges that are defined in the technology library.

Each time the **set_timing_ranges** command is used, it overwrites the previous specifications. To remove the timing ranges defined for the current design, use the **set_timing_ranges** command with no parameters, or use the **reset_design** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

To check a library for timing ranges, use the following command:

```
prompt> report_lib test_lib
.
.
.

Timing ranges:
Name          Library      slower_factor      faster_factor
-----        -----       -----
BEST_CASE     test_lib     0.98                0.96
WORST_CAS    test_lib     1.1                 1.0
```

In the following example, timing ranges from "my_lib.db" for the current design are selected:

```
prompt> read my_lib.db
prompt> set_timing_ranges WORST_CASE -library my_lib.db
```

The following example specifies two timing ranges for the current design if the **link_library** is "other_lib.db" and there is no **local_link_library** set on the current design:

```
prompt> set_timing_ranges {WORST_CASE BEST_CASE}
```

SEE ALSO

`report_timing(2)`
`reset_design(2)`
`set_local_link_library(2)`
`link_library(3)`

set_tlu_plus_files

Sets the files used for TLUPlus extraction.

SYNTAX

```
int set_tlu_plus_files
[-max_tluplus max_tluplus_string]
[-min_tluplus min_tluplus_string]
[-max_emulation_tluplus max_emul_string]
[-min_emulation_tluplus min_emul_string]
[-tech2itf_map mapping_file]
```

Data Types

<i>max_tluplus_string</i>	string
<i>min_tluplus_string</i>	string
<i>max_emul_string</i>	string
<i>min_emul_string</i>	string
<i>mapping_file</i>	string

ARGUMENTS

-max_tluplus *max_tluplus_string*
Specifies the TLUPlus file used for maximum condition calculation of resistance and capacitance using TLUPlus.

-min_tluplus *min_tluplus_string*
Specifies the TLUPlus file used for minimum condition calculation of resistance and capacitance using TLUPlus.

-max_emulation_tluplus *max_emul_string*
Specifies the emulation TLUPlus file used for maximum condition calculation of resistance and capacitance using TLUPlus.

-min_emulation_tluplus *min_emul_string*
Specifies the emulation TLUPlus file used for minimum condition calculation of resistance and capacitance using TLUPlus.

-techtf_map *mapping_file*
Specifies the layer name mapping file between the technology library and the Interconnect Technology Format (ITF) file. This switch is optional only if the names are the same.

DESCRIPTION

This command specifies the files used for virtual route and postroute extraction using TLUPlus. At a minimum, you must specify the maximum TLUPlus file and the mapping file.

The **-min_tluplus** option is optional and, if specified, the command runs an extraction for the minimum condition, as well.

The **-tech2itf_map** option maps from layer names in the technology library to the layer names in the Interconnect Technology Format (ITF) file. It should contain at least two sections, `conducting_layers` and `via_layers`; `conducting_layers` maps a `routing_layer` to a conductor layer in ITF, and `via_layers` maps a `contact_layer` to a via layer in ITF. If the names between your technology library and ITF file are the same, you do not have to specify this option. If you do not specify this option, the tool assumes that the names are the same. Thus, if the names are actually different, the tool will error out later.

You can also use this command to define two (optional) emulation TLUPplus files, which are used to perform emulation metal fill extraction. Emulation TLUPplus files include metal fill-related information, such as `FILL_RATIO`, `FILL_SPACING`, `FILL_WIDTH`, and `FILL_TYPE`.

If you use the same names in the different directorys for max and min `tlu_plus_file`, then they will be considered to be the same file. The file names need to be different if the files are not the same.

Note that tlu plus files are stored as physical attributes of the design. Design without floorplan is considered logical design. When open a logical design, only logical attributes are reloaded. It is important to do `initial_foorplan` or `read_def` after tlu plus file setting before save, to insure when reopen the physical attributes are reloaded.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example has, in the physical library:

```
routing_layer ( "METAL1" ) { ...  
}  
contact_layer ( "VIA1" );  
...
```

and has in the Interconnect Technology Format (ITF) file:

```
CONDUCTOR metal1 {THICKNESS=0.53 WMIN=0.23 SMIN=0.23 RPSQ=0.078 \  
CAPACITIVE_ONLYETCH=0}  
...  
VIA via1 {FROM=metal1TO=metal2 AREA=0.0169 RPV=1.6}
```

Thus, the mapping file should look like the following:

```
conducting_layers  
METAL1 metal1  
...  
via_layers
```

```
VIA1 vial
...
}
```

The following example has the same ITF file in the first example, so the mapping file should be the same as in the first example, too, if you have the following information in the Interconnect Technology Format (ITF) file:

```
Layer "METAL1" { maskName = "metall1"
...
}
Layer "VIA1" { maskName = "vial"
...
}
```

The following example runs the **set_tlu_plus_files** command.

```
prompt> set_tlu_plus_files -max_tluplus tlu.max \
-tech2itf_map design.map
```

SEE ALSO

```
extract_rc(2)
set_extraction_options(2)
```

set_true_delay_case_analysis

Sets the `true_delay_case_analysis` attribute, which specifies the input vector value to use for specified pins or ports of the current design with the `-true` and `-justify` options of `report_timing`.

SYNTAX

```
status set_true_delay_case_analysis
0 | 1 | r | f | none
port_pin_list
```

Data Types

`port_pin_list` list

ARGUMENTS

0 | 1 | r | f | none

Specifies the transition value at which to set the `true_delay_case_analysis` attribute. The first 4 arguments represent transition values and `none` removes the attribute. The valid transition values are `0` (logic 0), `1` (logic 1), `r` (rise, X to 1), and `f` (fall, X to 0). For details on these values, see the DESCRIPTION section below.

`port_pin_list`

Specifies a list of port or pin names of the current design for which the `true_delay_case_analysis` attribute is to be set. If more than one object is specified, they must be included in braces `({})`.

DESCRIPTION

The `set_true_delay_case_analysis` command sets the string attribute `true_delay_case_analysis` to 1 of 4 transition values, or removes the attribute if set to `none`. The attribute can also be removed with the `remove_attribute` command.

Case analysis is normally used on path startpoints, which are input ports and clock pins of registers. Internal pins can also be preset. They are then considered to be path startpoints (no signals propagate through them).

The `-justify` and `-true` options of `report_timing` attempt to prove that timing paths in the design are true by finding an input vector that sensitizes the paths. The `set_true_delay_case_analysis` command can be used to explicitly specify some values in the input vector. Setting a case analysis value at a pin blocks paths through that pin, so no value should be specified for pins on the path being sensitized.

By default, the true delay algorithm searches for full input vectors. However, you can preset all or part of the input vector manually using the `set_true_delay_case_analysis` command. Presetting part of the input vector can dramatically reduce the search space, which makes runtimes faster. You can also use `set_true_delay_case_analysis` to manually sensitize particular paths.

Note that **r** defines a rising value and **f** defines a falling value. These values are the X to 1 and X to 0 transitions applied at the inputs. In **report_timing -true** or **report_timing -justify**, the input vector is also reported this way, using **r** and **f** for the input transitions. On the report, an asterisk (*) identifies values that have been preset.

You can set signals to a constant value using the **0** and **1** arguments. This is different from the X to 1 and X to 0 transition that **r** and **f** imply. A constant value means that the signal is always 1 or 0.

To see the difference between presetting an **r** and presetting a **1**, consider the case of an OR gate that has an early-arriving controlling value **r** on one input, and the other input is a late-arriving preset value. Although the preset value was **r**, the earlier controlling value still propagates because the **r** is just a later arriving controlling value. However, if the preset value was a **1** then the output of the gate is a constant **1**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command specifies that the input vector will consider only rising transitions at port C for the purposes of **report_timing -true** or **report_timing -justify**:

```
prompt> set_true_delay_case_analysis r C
```

This example sets port A to a constant logic zero for **report_timing -true** or **report_timing -justify**:

```
prompt> set_true_delay_case_analysis 0 A
```

SEE ALSO

```
current_design(2)  
remove_attribute(2)  
report_timing(2)  
reset_design(2)
```

set_unconnected

Lists output ports to be unconnected.

SYNTAX

```
int set_unconnected  
port_list
```

Data Types

port_list list

ARGUMENTS

port_list

A list of port names in the current design that are to be left unconnected. If more than one port is specified, they must be enclosed either in quotes or in braces ({}).

DESCRIPTION

Assigns an **output_not_used** attribute to ports in *port_list*. This information is used by **compile** to create smaller designs by eliminating logic that drives an unconnected output port and therefore might not need to be maintained during optimization. After a design with an unconnected output port is compiled, the port usually is not driven by anything inside the design.

This attribute can be removed using the **remove_attribute** command.

Note: The **set_unconnected** command cannot be used on input ports. Input ports can be tied to logic one, logic zero, or don't-care using **set_logic_one**, **set_logic_zero**, and **set_logic_dc**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies that output ports "CARRY_OUT" and "err_1" are not to be used.

```
prompt> set_unconnected {CARRY_OUT err_1}
```

SEE ALSO

```
get_attribute(2)  
remove_attribute(2)  
report_port(2)
```

```
reset_design(2)
set_logic_one(2)
set_logic_zero(2)
set_logic_dc(2)
```

```
set_unconnected
2702
```

set_undoable_attribute

Sets an attribute to a specified value on the specified list of objects with support for undo.

SYNTAX

```
collection set_undoable_attribute
[-class class_name]
object_list
attribute_name
[-quiet]
```

Data Types

<i>class_name</i>	string
<i>object_list</i>	string_list
<i>attribute_name</i>	string

ARGUMENTS

-class *class_name*
Specifies the class name for the object specified in *object_list*, if the element of *object_list* is a name. Valid classes are design, port, cell, net, etc.

object_list
A list of objects on which the attribute is to be set. Each element in the list is either a collection or a pattern that is combined with the *class_name* to find the objects.

attribute_name
Specifies the name of the attribute to be set.

-quiet
Turns off the warning message that would otherwise be issued if the attribute or objects are not found.

RETURNS

collection
collection of objects affected

DESCRIPTION

This command sets the value of an attribute on an object. For a complete listing of attributes, refer to the attributes man page.

This command creates a collection of objects that have the specified attribute value set. A returned empty string indicates that no object has been set.

The resultant attribute value change can be undone using the undo command

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example defines an attribute named X for cells, then sets the value on all cells in this level of the hierarchy:

```
prompt> define_user_attribute -type int -class cell Xcell
prompt> set_undoable_attribute [get_cells *] X 30{"U1"}
```

SEE ALSO

```
collections(2)
define_user_attribute(2)
get_attribute(2)
list_attributes(2)
remove_attribute(2)
set_attribute(2)
undo(2)
```

set_ungroup

Sets the **ungroup** attribute on specified designs, cells, or references, indicating that they are to be ungrouped during **compile**.

SYNTAX

```
int set_ungroup  
object_list true | false
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of cells, references, or designs to be ungrouped during **compile**.

true | false

The value with which to set the **ungroup** attribute. The default is *true*.

DESCRIPTION

Sets the **ungroup** attribute on the specified objects so that they are ungrouped (collapsed to one design level) before they are optimized. The **compile** command does not ungroup cells or designs with the **dont_touch** attribute.

This attribute is removed with the **remove_attribute** or **reset_design** commands.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the first example, the **ungroup** attribute is set on the cell "U1".

```
prompt> set_ungroup U1
```

If the **ungroup** attribute is specified on a reference object, cells using that reference are ungrouped during **compile**. In this example, all the instances of ADDER in the current design are ungrouped.

```
prompt> set_ungroup [get_references ADDER]
```

A design with this attribute is ungrouped whenever **compile** encounters it.

```
prompt> set_ungroup [get_designs ND17]
```

SEE ALSO

`current_design(2)`
`remove_attribute(2)`
`reset_design(2)`
`ungroup(2)`
`ungroup_keep_original_design(3)`

set_units

Sets the units used for resistance, capacitance, timing, leakage power, current and voltage. The units must be consistent with the main library units.

SYNTAX

```
string set_units
[-resistance ohm|kohm|mohm|Mohm|10ohm|100ohm]
[-capacitance f|ff|pf|nf|uf|mf|10ff|100ff]
[-time s|fs|ps|ns|us|ms|10ps|100ps]
[-power w|fw|pw|nw|uw|mw|10uw|100uw|10mw|100mw|10pw|100pw|10nw|100nw]
[-current A|fA|pA|nA|uA|mA|10uA|100uA|10mA|100mA]
[-voltage v|fv|pv|nv|uv|mv|10mv|100mv]
```

ARGUMENTS

- resistance
Sets the resistance unit.
- capacitance
Sets the capacitance unit.
- time
Sets the time unit.
- power
Sets the power unit.
- current
Sets the current unit.
- voltage
Sets the voltage unit.

DESCRIPTION

The **set_units** command sets the units for SDC file. In the Z-2007.03 release, the units cannot conflict with the main library units; therefore, it is not recommended to not use the **set_units** command interactively.

When the tool writes an SDC file, the **set_units** command is always written out as the first SDC command. If no units are set, the tool gets the units from the main library (the first link library).

EXAMPLES

The following example specifies the **set_units** command that is written to the SDC file.

```
prompt> set_units -time ns -resistance kohm -capacitance pf \
```

```
-power uW -voltage V -current A <plain
```

SEE ALSO

`report_units(2)`

set_user_grid

Sets the user grid for this session.

SYNTAX

```
status set_user_grid
[-x_offset float]
[-y_offset float]
[-x_step float]
[-y_step float]
[-user_grid {{x_offset y_offset} {x_step y_step}}]
[-x_get_from_layer layer]
[-y_get_from_layer layer]
[-reset]
[design]
```

Data Types

<i>float</i>	floating-point
<i>layer</i>	collection
<i>design</i>	string

ARGUMENTS

-x_offset float
Specifies the horizontal (X) distance (in user units) by which you want to offset the cursor snap-to points from the grid point. The value must be multiple of litho grid. This option is exclusive with -user_grid and -x_get_from_layer option. You can only use one of them.

-y_offset float
Specifies the vertical (Y) distance (in user units) by which you want to offset the cursor snap-to points from the grid point. The value must be multiple of litho grid. This option is exclusive with -user_grid and -y_get_from_layer option. You can only use one of them.

-x_step float
Specifies the horizontal (X) distance (in user units) you want between cursor snap-to points. The value must be multiple of litho grid. This option is exclusive with -user_grid and -x_get_from_layer option. You can only use one of them.

-y_step float
Specifies the vertical (Y) distance (in user units) you want between cursor snap-to point. The value must be multiple of litho grid. This option is exclusive with -user_grid and y_get_from_layer option. You can only use one of them.

-user_grid {{x_offset y_offset} {x_step y_step}}
Specifies the user grid in list representation. The element value must be multiple of litho grid. This option is exclusive with all other options except design.

```

-x_get_from_layer layer
    Indicate to have the tool automatically calculate the user grid x_offset
    x_step from the wire track on the specified layer. The value could be layer
    name or layer number or layer collection. This option is exclusive with -
    x_offset -x_step and -user_grid option. You can only use one of them.

-y_get_from_layer layer
    Indicate to have the tool automatically calculate the user grid y_offset
    y_step from the wire track on the specified layer. The value could be layer
    name or layer number or layer collection. This option is exclusive with -
    y_offset -y_step and -user_grid option. You can only use one of them.

-reset
    Reset the user grid to litho grid. This option can only be used with design
    option.

design
    Specifies in which design to set the user grid information. If this option
    is not specified, it will set global user grid information which is used for
    default value of successive run of this command.

```

DESCRIPTION

This command set user grid for this session of the tool. You can use the -user_grid option to set the user grid in one shot. Or else, you can use -x_offset, -y_offset, -x_step, -y_step to specify individual part of the user grid. If any of these four options are not specified, then the corresponding value is not changed. Finally, you can use -x_get_from_layer and/or -y_get_from_layer to have the tool automatically calculate the user_grid from the wire track on the given layer.

The user grid must be multiple of litho grid. If it's not, this command will fail with error message MWUI-212.

If design is not specified, then this command will set global user grid. The global user grid will be used as default value for design specific user grid until you explicitly set user grid on the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example set global user grid in one shot:

```

prompt> set_user_grid {{0 0} {0.010 0.010}}
1

```

The following example set x_offset and y_offset of the global user grid only:

```

prompt> set_user_grid -x_offset 0.5 -y_offset 0.6
1

```

The following example set user grid from wire track information on given design top.

```
prompt> set_user_grid -x_get_from_layer M1 -y_get_from_layer M2 top  
1
```

The following example failed because the value specified is not multiple of litho grid, suppose litho grid is 0.001:

```
prompt> set_user_grid -x_offset 0.0005  
Error: Value '0.0005' is not multiple of litho grid '0.001'. (MWUI-212)  
0
```

SEE ALSO

[get_user_grid\(2\)](#)

set_via_array_size

Modifies the array size of an existing via or via array.

SYNTAX

```
collection set_via_array_size
-array_size {row col}
via_collection
```

Data Types

via_collection collection

ARGUMENTS

```
-array_size {row col}
    Specifies the new array_size of the via/via_array. The value of row and col
    must be positive integer. If you specify {1 1} to a via_array, the via_array
    will be converted to a via. If you specify another value except {1 1} to a
    via, the via will be converted to a via_array.
    You must specify this option.

via_collection
    Specifies a list of via/via_arrays that to be assigned with new array_size
    value.
```

DESCRIPTION

The **set_via_array_size** command enables you to convert a via to a via_array and vice versa. You may also use this command to change the value of array_size of a via_array. The return value is a collection contains the modified via/via_array.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example modifies a via to a via_array with array_size {2 3}

```
prompt> set_via_array_size -array_size {2 3} VIA#4075 {VIA_ARRAY#86054}
```

SEE ALSO

```
create_via(2)
get_vias(2)
remove_via(2)
```

set_voltage

Applies an operating voltage on a list of supply nets objects.

SYNTAX

```
int set_voltage
max_case_voltage
[-min min_case_value]
-object_list list_of_supply_nets
```

Data Types

max_case_voltage	float
list_of_supply_nets	list

ARGUMENTS

max_case_voltage
Specifies the operating voltage for the maximum (worst) case.

-min min_case_value
Specifies the operating voltage for the minimum (best) case.

-object_list list_of_supply_nets
Specifies the list of supply nets that will have the operating voltages as specified in this command. Collection input is supported.

DESCRIPTION

Defines the operating voltage on the supply nets and their corresponding power nets so that the parts of the design powered by these supply nets or power nets are timed and optimized at the specified voltage. If you do not specify any operating voltage for a supply net, the part of the design connected by this supply net will continue to be timed and optimized based on the available operating condition settings.

To see the operating voltages of supply nets, use **report_supply_net**.

The operating voltage of a supply net, once defined, can only be overridden with another **set_voltage**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows a typical context of use for the **set_voltage** command.

```
prompt> create_power_domain CNTL
```

```
1
prompt> create_supply_net sn1 -domain CNTL
1
prompt> create_supply_net sn2 -domain CNTL
1
prompt> set_voltage 0.9 -object_list {sn1 sn2}
1
```

SEE ALSO

`create_supply_net(2)`
`create_power_domain(2)`
`set_domain_supply_net(2)`
`connect_supply_net(2)`
`report_supply_net(2)`
`report_power_domain(2)`

set_vt_filler_rule

Sets multiple threshold voltage filler cell insertion rules.

SYNTAX

```
integer set_vt_filler_rule
-threshold_voltage
-lib_cell
```

ARGUMENTS

-threshold_voltage *vt_type_1 vt_type_2*

Specifies threshold voltage types to be used in a gap between two standard cells of *vt_type_1* and *vt_type_2*. The name *vt_type_1* and *vt_type_2* must be a string previously specified by the *set_cell_vt_type* command. If *vt_type_2* is omitted, it refers to the default vt type, referring to cells that have never been marked with any threshold voltage type.

-lib_cell *cell_list*

The collection *cell_list* refers to a collection of library cells. The specified library cells will be used as fillers between a gap characterized by *vt_type_1* and *vt_type_2*.

DESCRIPTION

Use this command to set multiple threshold voltage filler rules of the design. To specify the rule, the command *set_cell_vt_type* command should have been used to mark the threshold voltage type of a standard cell. The insertion rule is used by the *insert_stdcell_filler* command. Only the specified filler cells will be inserted in a gap characterized by *vt_type_1* and *vt_type_2*. The relative position of the two standard cell types is not important. A gap with *vt_type_1* on the left and *vt_type_2* on the right is the same as that with the two types switched. Cells not marked with any threshold voltage type have the "default threshold voltage type" which is a valid type by itself.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies a filler rule between library cells of "vtTypeA" and "vtTypeB", and uses filler cells f1, f2, or f3.

```
prompt> set_vt_filler_rule -lib_cell {f1 f2 f3} \
          -threshold_voltage {vtTypeA vtTypeB}
```

SEE ALSO

[-ignore_layer_mapping_for_imported_cells]
```

Data Types

<i>layer_mapping_file_name</i>	string
<i>cell_renaming_file_name</i>	string
<i>list_of_types</i>	list of strings
<i>di_struct_name</i>	string
<i>di_layer_mapping_file_name</i>	string

ARGUMENTS

-reset

Resets all options to their default value.

-map_layer layer_mapping_file_name
 Specifies the file that defines the layer mapping from Milkyway to GDSII.
 The layer mapping file format is
 MWObjType[:MWNetType][PinCode]
 MWLayer[:MWDataType] GDSLayer[:GDSDaTaType]
 Valid values for MWObjType are
 * A for all types
 * T for text
 * D for data
 Valid values for MWNetType are
 * A for all types
 * S for signal
 * P for power
 * G for ground
 * C for clock
 * U for up conduction layer (upper layer in a via)
 * D for down conduction layer (lower layer in a via)
 * X for power or ground wires or contacts with a "signal"
 or "tie-off" routing type
 Valid values for PinCode are
 * P means that the pins on each CEL view cell being
 processed, which might include child cells depending on
 the value of the **-child_depth** option, are mapped
 by this rule.
 * T means that only the top-level pins (terminals) on the
 current top-level cell are mapped by this rule.
 * null
 For example, to map the text associated with signal nets on Milkyway layer
 10 with a data type of 20 to GDS layer 22 with a data type of 1, enter
 TS 10:20 22:1
 To map the geometry of METAL1 terminals to GDS layer 15:2 and map the geometry
 of lower-level METAL1 pins (not terminals) to GDS layer 14:2, enter
 DSP METAL1 14:2
 DAT METAL1 15:2
 By default, **write_stream** uses the layer information defined in the Milkyway
 database.

-rename_cell cell_renaming_file_name
 Specifies the file that contains the mapping from original cell names to new
 cell names. This option is for GDS only.
 The name mapping file format is
 OldCellName NewCellName
 For example, to map TOP.CEL to NEWTOP.CEL, enter
 TOP NEWTOP
 By default, the original cell names are output.

-child_depth child_cell_depth
 Specifies the hierarchical level to output child cells. To export all child
 cells, you should specify a large number, such as 20. Milkyway exports the
 CEL view of each child cell to the specified level of hierarchy.
 The default value is 0, meaning only the top-level cell is output.

-skip_ref_lib_cells
 Skips the conversion of child cells in reference libraries. This option is
 for GDS only.

set_write_stream_options

2718

By default, **write_stream** converts all the referenced child cells from the reference libraries.

-resize_text {width text_conversion_factor}

Specifies the text width in user units and the conversion factor for the text height relative to its width in Milkyway.

The default value is 1.0 for *text_conversion_factor* and 0.0 for *width*.

-flatten_via

Breaks down contacts and contact arrays into component parts.

By default, **write_stream** does not flatten contacts and contact arrays.

Instead, it translates contacts as references, outputs contact geometry as cells, and creates cells with the following naming convention for a contact array: "prefix_contactName_xViaPitch_yViaPitch_xReps_yReps", where "prefix" is the prefix specified in the **-contact_prefix** option, "contactName" is the name assigned to the contact in the deviceTable section in the Milkyway technology file, "xViaPitch" is the horizontal distance in database units between centers of contacts in the array, "yViaPitch" is the vertical distance in database units between centers of contacts in the array, "xReps" is the number of columns (contacts in the horizontal direction) in the array, and "yReps" is the number of rows (contacts in the vertical direction) in the array. For example, `$$VIA1_2000_3000_4_4`.

-contact_prefix \$\$

Specifies the prefix added to contact or contact array names.

The default is "\$\$".

-output_filling {list_of_types}

Specifies the types of filling data to output. Valid values are

* notch

Outputs notch data stored in the NOTC view.

* gap

Outputs gap data stored in the GAP view.

* fill

Outputs fill data stored in the FILL view.

You can specify multiple types.

By default, no filling data is output.

-output_outdated_fill

Forces the output of fill data even if the fill data is out-of-date.

By default, out-of-date fill data is not output.

-output_instance_name_as_property inst_prop_value

Specifies the instance property integer (1-127) to attach a property to each object associated with cell instances in the design.

By default, the instance property is not generated.

-output_geometry_property

Outputs a geometry's property.

By default, the property attached to a geometry is not written out. This option is for GDS only.

-remove_backslash_from_instance_net_names

Removes backslashes from cell instance and net names where backslashes can be inserted. For example, a backslash can be inserted before a bus character

or hierarchy character as an escape.

-max_name_length max_name_length
 Specifies the name length limit for all output cells. If the cell name exceeds the length limit, **write_stream** truncates the cell name and resolves the new name conflict automatically. The default length is 32.
 Note that this option is for library cell names only. To set a name length limit for instance names or net names, use the **-set_hier_instance_name_long** or **-set_hier_net_name_long** options.
 This is for GDS only.

-keep_data_type
 Keeps each object's data type as defined in the Milkyway library. By default, **write_stream** converts the data type to 0. This option is for GDS only.

-output_by_layer {layer_number_strings}
 Specifies the layers for which to output the geometry and text. You specify the layers and data types to output in the following format:
 {layer1[:datatype1] layer2[:datatype2] ...}
 Separate different layers by a space. For example,
 {3 4 5 11:10}
 This option is for GDS only.

-oasis_compression_level compress_level_value
 Specifies the compression level (1-9) to compress the resulting stream file. By default, **write_stream** generates the resulting stream file without compression. This option is for OASIS only.

-compressed
 Compresses the resulting stream file in gzip format. By default, **write_stream** generates the resulting stream file without gzip compression. This option is for GDSII only.

-output_pin {output_pin_types}
 Specifies the object types to output for each pin. Valid values are:
 * **text**
 Outputs the name of each pin as a TEXT object associated with the pin.
 * **geometry**
 Outputs the geometry of each pin as a POLYGON or BOUNDARY object associated with the pin.
 This option is for GDS only.

-pin_name_mag pin_name_mag
 Specifies the magnification for text when outputting a pin as a TEXT object. The default value is 1.0. This value takes effect only when **-output_pin {text}** is specified. This option is for GDS only.

-net_name_mag net_name_mag
 Specifies the magnification for text when outputting a net as a TEXT object. The default value is 1.0. This value takes effect only when **-output_net {text}** is specified. This option is for GDS only.

-output_net {output_net_types}
 Specifies the object types to output for each net. Valid values are:
 * **text**

Outputs the name of each net as a TEXT object associated with the net.

* **plex**
Assigns a plex number to each net and generates a text record with the plex number. When you specify **plex**, it automatically selects **text**, as well.
This option is for GDS only.

-output_net_name_as_property net_prop_value
Specifies the net property integer (1-127) to attach a property to each object associated with cell nets in the design. By default, the net property is not generated.

-output_polygon_pin
Outputs pin geometries that are not rectangles. By default, nonrectangular pin geometries are not output. This option is for GDS only.

-output_design_intent
Outputs design intent data. By default, design intent data is not output, even if you specify design-intent-related options. This option is for GDS only.

-design_intent_cell_name di_struct_name
Specifies the struct name to hold design intent data. Default value is "DesignIntent". This option is for GDS only.

-critical_object_names critical_inst_net_name_list
Specifies the file name of the critical nets and cell instances. The critical name list is in ASCII format with each name entry on a separate line prefixed by N for net or I for instance. In each name list, net and instance names are grouped by level of criticality with the DITYPE keyword. For example,

```
-----
DITYPE CRITICAL_10_PERCENT
N INST1/NET12
N INST1/NET15/Q
I INST2
DITYPE EM_SENSITIVITY
N INST1/NET12
N INST2/net14/q
I INST3
-----
```

This option is for GDS only.

-map_design_intent_layers di_layer_mapping_file_name
Specifies the file name of the design intent layer mapping. The file contains the mapping between the original design layer-datatype pairs and design intent layer-datatype pairs. The layer mapping is grouped by level of criticality with DITYPE keyword. The design intent layer mapping format is N|I original_layer:original_datatype->DI_layer:DI_datatype
For example,

```
-----
DITYPE CRITICAL_10_PERCENT
N 31:0->31:0 ; Metal 1 critical net
I 255:0->64:10 ; instance marking for critical design intent

DITYPE EM_SENSITIVE_NETS
```

```

N 31:0->31:15 ; Metal 1 EM design intent
N 32:0->32:15 ; Metal 2 EM design Intent
-----
This option is for GDS only.

-design_intent_only
    Outputs only design intent data. By default, write_stream outputs original
    design data along with the design intent data. This option is for GDS only.

-rotate_pin_text_by_access_dir
    Rotates a pin's TEXT object according to the pin's access direction. By
    default, the TEXT object is not rotated. This option takes effect only when
    -output_pin {text} is specified. This option is for GDS only.

-set_hier_instance_name_long
    Specifies the name length limit of the output instance name is longer than
    126 characters. This option is for GDS only.

-set_hier_net_name_long
    Specifies the name length limit of the output net name is longer than 126
    characters. This option is for GDS only.

-ignore_layer_mapping_for_imported_cells
    Turn this option on to ignore layer mapping for those cells created from GDSII
    file. The layer number will be written exactly to GDSII file without any
    conversion.

```

DESCRIPTION

The **set_write_stream_options** command sets the options for the **write_stream** command. The command is additive; you can run it multiple times to incrementally set the options. You can report the option values by using the **report_write_stream_options** command. The options set by **set_write_stream_options** are modal. Once set, the values are not changed until next set.

Multicorner Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets a child cell depth of 1 and outputs gap data.

```

prompt> set_write_stream_options \
-child_depth 1 \
-output_filling {gap}

```

SEE ALSO

write_stream(2)
report_write_stream_options(2)

set_write_stream_options

2722

set_xtalk_route_options

Sets global route and track assignment crosstalk options.

SYNTAX

```
status set_xtalk_route_options
[-default]
[-groute_minimize_xtalk true | false]
[-groute_xtalk_weight number]
[-track_assign_minimize_xtalk true | false]
[-track_assign_noise_threshold value]
```

Data Types

<i>number</i>	integer
<i>value</i>	float

ARGUMENTS

```
-default
    Set default options

-groute_minimize_xtalk true | false
    Global route xtalk mode (default is false).

-groute_xtalk_weight number
    Global route xtalk weight (default is 4). Range: 0 to 16.

-track_assign_minimize_xtalk true | false
    Track assign xtalk mode (default is false).

-track_assign_noise_threshold value
    Noise threshold ratio to supply voltage (default is 0.45). Range: 0 to 1.
```

DESCRIPTION

This command allows you to set global route and TrackAssignment xtalk options for use by subsequent router steps. This options can also be set by `set_parameter` commands.

Many of the options have a (true | false) syntax because it may be necessary to set the option true if it was originally set to false, or it may be necessary to set it to false if it was set previously to true.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> set_xtalk_route_options\
-track_assign_minimize_xtalk true
```

SEE ALSO

[set_parameter \(2\)](#)

set_zero_interconnect_delay_mode

Forces the timer to ignore the contribution on a timing path from any wire capacitance in the design.

SYNTAX

```
status set_zero_interconnect_delay_mode
[true | false]
```

ARGUMENTS

true | false

Enables the zero interconnect delay mode when set to **true**. Disables the zero interconnect delay mode when set to **false**. If no value is specified, the default is **true**.

DESCRIPTION

This command enables or disables the zero interconnect delay mode. The zero interconnect delay mode forces the timer to ignore contributions on a timing path from any wire capacitance in a design. It forces all wire capacitance to be as trivial as 0, regardless of the wire load model used in the design or any back-annotated capacitance on a wire. Disabling the mode allows the timer to consider the wire capacitance as it did before enabling the mode.

The command is used primarily in preplacement and postplacement steps to assess design and constraint feasibility. When the mode is enabled, the design is analyzed with only cell delay and the capacitance of the pin load on all wires in the design to determine if the design can meet timing goals. It also helps when debugging potential missing timing exceptions in the constraints. Zero interconnect delay mode must not be used in the final implementation step.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

```
get_zero_interconnect_delay_mode(2)
report_timing(2)
```

set_zrt_net_properties

Sets net properties for Zroute.

SYNTAX

```
status set_zrt_net_properties
[-ignore_voltage_areas true | false]
-nets collection_of_nets
-from_file file_name
```

Data Types

collection_of_nets collection

ARGUMENTS

```
-ignore_voltage_areas true | false
    Controls whether the router should ignore voltage area constraint for the
    specified nets.
    The default value is false.

-nets collection_of_nets
    Specifies the list of nets to set the properties to. Nets must be specified
    by -nets or -from_file.

-from_file file_name
    Specifies the nets by name in the file. Nets must be specified by -nets or -
from_file.
```

DESCRIPTION

The **set_zrt_net_properties** command sets properties on specified list of nets. Zroute then honors the properties as it performs routing.

EXAMPLES

The following example sets a list of nets that do not need to satisfy the voltage area constraint:

```
prompt> set_zrt_net_properties -nets {n1 n2 n3} -ignore_voltage_areas true
```

SEE ALSO

```
get_zrt_net_properties(2)
report_zrt_net_properties(2)
```

setenv

Sets the value of a system environment variable.

SYNTAX

```
string setenv
variable_name new_value
```

Data Types

variable_name	string
new_value	string

ARGUMENTS

variable_name
Names of the system environment variable to set.

new_value
Specifies the new value for the system environment variable.

DESCRIPTION

The **setenv** command sets the specified system environment *variable_name* to the *new_value* within the application. If the variable is not defined in the environment, the environment variable is created. The **setenv** command returns the new value of *variable_name*. To develop scripts that interact with the invoking shell, use **getenv** and **setenv**.

Environment variables are stored in the Tcl array variable **env**. The environment commands **getenv**, **setenv**, and **printenv** are convenience functions to interact with this array.

The **setenv** command sets the value of a variable only within the process of your current application. Child processes initiated from the application using the **exec** command after a usage of **setenv** inherit the new variable value. However, these new values are not exported to the parent process. Further, if you set an environment variable using the appropriate system command in a shell you invoke using the **exec** command, that value is not reflected in the current application.

EXAMPLES

The following example changes the default printer.

```
prompt> getenv PRINTER
laser1
prompt> setenv PRINTER "laser3"
laser3
prompt> getenv PRINTER
laser3
```

SEE ALSO

`getenv(2)`
`printenv(2)`
`printvar(2)`

shape_fp_blocks

Automatically places and shapes plan group boundaries, black boxes, and other soft macros in a design core.

SYNTAX

```
status shape_fp_blocks
[-rectilinear]
[-incremental target_utilization_driven | congestion_driven]
[-channels]
[-refine_placement]
[-constraint_file file_name]
[-top_down]
[-sliver_threshold threshold]
[-place_submacros]
```

Data Types

<i>file_name</i>	string
<i>threshold</i>	float

ARGUMENTS

-rectilinear

If you do not select this option, the command creates only rectangular plan groups or soft macro boundaries unless they would overlap fixed objects, in which case the shape might need to be rectilinear if it needs to be cut out around the fixed objects.

If you select this option, then in cases where one small block and one large block need to be shaped close to each other, the small block is placed in one of the corners of the large block, creating a rectilinear L-shaped boundary. Therefore, L-shaped plan groups can be created even if no fixed objects are encountered on the floorplan.

The default is off.

-incremental target_utilization_driven | congestion_driven

Adjusts the floorplan to meet new target plan group and voltage area utilizations or to reduce congestion in channels between blocks or inside the blocks themselves. The command incrementally modifies the sizes, shapes, and locations of plan groups and voltage areas in the design.

If you specify the target_utilization_driven mode, the command tries to decrease the plan group and voltage area utilizations to be at most the sum of the corresponding target utilizations and the value of the blockPlace_utilSlack variable. It first attempts to keep the utilizations at or below the target utilization, but will allow a slightly higher value as long as the difference is not more than the blockPlace_utilSlack variable. Utilizations that are below the target ones are considered acceptable and therefore the command does not attempt to increase utilizations to match the target ones.

If you specify the congestion_driven mode, the command first attempts to use the congestion map created by global routing. If one is not available, it tries to use a placement congestion map. If neither congestion map is

available, an error message is generated. Once a congestion map exists, you can use it to estimate the required sizes of the channels and blocks that will be needed to help reduce congestion. The channels and blocks are resized and reshaped to reduce congestion in the channels between blocks and inside the blocks themselves so that the estimates based on the congestion map are satisfied. The objective is to reduce congestion by resizing the channels as close to an optimal width as possible based on the existing congestion map. The default is off.

-channels

Use this option if you want to create routing channels between plan groups, black boxes, and soft macros. The channel widths are based on pin counts with nonperpendicular connections to objects on the associated object edge. The default is off.

-refine_placement

If you select this option, the command will refine the placement after it performs placement and shaping of all unfixed plan groups, soft macros, and black boxes in the design. The effect is the same as running the `create_fp_placement` command without any arguments. The default is off.

-constraint_file *file_name*

If you select this option, you must enter the name of the file that contains the path and name of an ASCII file containing relative placement constraints to guide the placement and shaping of objects. The format of the constraint file is one constraint per line. The first word in the line is always the name of the constraint. For example,

`fplModuleDestRegion plan_group_name region_abbrev`

where `region_abbrev` is one of N, S, E, W, NE, NW, SE, SW; S stands for south, and so forth.

For a description of the relative placement constraints, see the section on "Using Relative Placement Constraints to Guide the Placement and Shaping of Objects" in Chapter 6 of the IC Compiler User Guide: Design Planning.

-top_down

If you select this option, the command sets variables prior to running so that the placement and shaping of objects is constrained like top down placement (`fphBlockPlacement` command) in JupiterXT. Initial virtual flat placement is not assumed with this option. If the `-channels` option is on, the command tries to maintain the block area. After the command runs, any variables it set are restored to their previous settings. The default is off.

-sliver_threshold *threshold*

If you select this option, placement areas between blockages or fixed objects or both, which are smaller than the input value in microns are blocked out during shaping. This avoids "skinny fingers" that can occur when there are many blockages or when there are blockages with small channels between each other or the design core. By default, the value is -1, which means that the tool will automatically calculate a reasonable value for this option.

-place_submacros

If you select this option, the command places hard macros in the top-level cell and in all unfixed soft macros. The default is off.

DESCRIPTION

This command automatically places and shapes plan group boundaries, black boxes, and other soft macros in a design core. It assumes that an initial virtual flat placement has already been run on the design. You can also use this command to refine channels if a congestion map has been created. The command returns 0 if it fails, 1 if it succeeds in reshaping the blocks. If no action was necessary (this happens only with -incremental option), the command returns 2.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example places and shapes objects with all default options.

```
prompt> shape_fp_blocks
```

The following example resizes channels between already placed plan groups/soft macros to match the existing congestion map.

```
prompt> shape_fp_blocks -incremental congestion_driven
```

The following example places and shapes plan groups/soft macros while obeying the constraints specified in the file named myConstraints.

```
prompt> shape_fp_blocks -constraint_file myConstraints
```

SEE ALSO

`create_fp_placement(2)`

shell_is_in_upf_mode

Determines if the shell is in UPF mode.

SYNTAX

```
status shell_is_in_upf_mode
```

ARGUMENTS

The **shell_is_in_upf_mode** command has no arguments.

DESCRIPTION

This command is used to check if the shell is in UPF mode. The command returns 1 if shell is in UPF mode, or 0 otherwise. In 2008.09, UPF mode is on by default. To use non-UPF mode, invoke dc_shell or icc_shell with -non_upf_mode.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to determine the mode in which the shell has been invoked:

```
prompt> if {[shell_is_in_upf_mode]} {\  
           echo "You invoked dc_shell in UPF mode" \  
} else {\  
           echo "You invoked dc_shell in non-UPF mode" \  
}
```

signoff_drc

Detects 65nm and below process design rule checking (DRC) violations with foundry runset.

SYNTAX

```
status signoff_drc
[-error_view errview_name]
[-check_all_layers]
[-read_cel_view]
[-ignore_child_cell_errors]
[-select_layers {collection_of_layers}]
[-select_rule {list_of_rule_names}]
[-unselect_rule {list_of_rule_names}]
[-bounding_boxes {{llx1 lly1} {urx1 ury1} ...}]
[-excluded_bounding_boxes {{llx1 lly1} {urx1 ury1} ...}]
[-run_dir string]
[-num_cpus integer]
```

Data Types

<i>errview_name</i>	string
<i>collection_of_layers</i>	collection
<i>list_of_rule_names</i>	list
<i>llx1</i>	float
<i>lly1</i>	float
<i>urx1</i>	float
<i>ury1</i>	float
<i>string</i>	errview_name

ARGUMENTS

-error_view errview_name

Specifies the name of the err view. If the option is missing, <current_cell_name>_sdrc.err is used by default.

-check_all_layers

Performs DRC on all layers (including routing layers, device layers, and so on) defined in the runset. Only routing layers (metal and via layers) are checked when this option is off. This option is off by default.

-read_cel_view

Reads the data of cell instances from the CEL view. If the CEL view of a cell instance cannot be found, the command stops. When this option is off (default), cell instances are read from the FRAM view. If the FRAM view of a cell instance cannot be found, the command ignores this cell instance for DRC and continues to check other cell instances. The command gives a warning message for the ignored cell instance in the error file.

-ignore_child_cell_errors

Set this option to skip the DRC violations inside all cell instances (reference libraries). This option is off by default.

```

-select_layers {collection_of_layers}
    Specifies a list of routing layers (metal or via layers) to perform design rule checking. The names of layers must be the names defined in the technology file. By default, all routing layers are checked when the option -check_all_layers is off.

-select_rule {list_of_rule_names}
    Specifies either a rule name/pattern or numbers of rule names/patterns to perform DRC. These rule names/patterns are declared in the COMMENT option of foundry runset. If the option is missing, all design rules are checked by default.

-unselect_rule {list_of_rule_names}
    Specifies the rule name(s)/pattern(s) to exclude DRC. These rule names/patterns are declared in the COMMENT option of foundry runset. If the option is missing, no design rules are excluded by checking.

-bounding_boxes {{llx1 lly1} {urx1 ury1} ...}
    Specifies either an area or areas to perform design rule checking. An area is a collection of two points coordinates that specify the lower-left and upper-right corners. The units of the coordinates are the main library units. This option is off by default.

-excluded_bounding_boxes {{llx1 lly1} {urx1 ury1} ...}
    Specifies either an area or areas to exclude design rule checking. An area is a collection of two points coordinates that specify the lower-left and upper-right corners. The units of the coordinates are the main library units. This option is off by default.

-run_dir string
    Specifies the path of working directory. Default is signoff_drc_run directory under current working directory. The path can be either relative or complete.

-num_cpus integer
    Specifies the number of CPUs for distributed processing. The number of CPUs should be greater than or equal to 1. The default value comes from the setting of the command set_physical_signoff_options.

```

DESCRIPTION

This command detects 65nm and below process DRC violations. It launches IC Validator (ICV) or Hercules with foundry runset to do design rule checking (DRC). Before running this command, you must provide the environment setting for ICV or Hercules by using the **set_physical_signoff_options** command. For a more detailed description of ICV or Hercules, see the *ICV Reference Manual* or *Hercules Reference Manual*.

All options are optional.

Note

The **-check_all_layers** option needs to be run after routing layers only (default) option got DRC clean. The **-read_cel_view** option will be automatically turned on for this option and all lower level errors will be flattened to the top level.

The **-check_all_layers** option does not work if your reference libraries (child cells) have only a FRAM view. This option is supported only when reference libraries have a CEL view.

The **-check_all_layers** and **-select_layers** options are mutually exclusive; you can specify only one.

When both **-select_rule** and **-unselect_rule** options are used concurrently, the **-unselect_rule** unselects rule(s) from the selected ones. Similarly, the **-excluded_bounding_boxes** option also excludes DRC checking based on the selected region(s) by **-bounding_boxes** option if both options are applied at the same time.

When you use the **signoff_drc** command for DRC checking, you must provide reference libraries (child cells data) with DRC clean.

Warning

ICV or Hercules runs hierarchically and reports errors in the top level by expanding the lower-level errors without merging them for the purpose of the IC Compiler error browser.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the command with two patterns of rule names *M*.W.1* and *M*.W.3*.

```
prompt> signoff_drc -select_rule {M*.W.1 M*.W.3}
```

The following example runs the command excluding one pattern of rule name *VIA*.S*.

```
prompt> signoff_drc -unselect_rule {VIA*.S}
```

The following example runs the command within the bounding box (42.67 98.85) (125.39 157.16).

```
prompt> signoff_drc -bounding_boxes {{42.67 98.85} {125.39 157.16}}
```

SEE ALSO

```
report_physical_signoff_options(2)
set_physical_signoff_options(2)
verify_drc(2)
verify_route(2)
```

signoff_metal_fill

Invokes Hercules or IC Validator to perform metal fill on current cells to meet the metal density requirements.

SYNTAX

```
status signoff_metal_fill
[-output_view fillview_name]
[-purge]
[-eco]
[-append]
[-mode flat]
[-select_layers {layer_name}]
[-bounding_boxes {rectangle_list}]
[-excluded_bounding_boxes {rectangle_list}]
[-run_dir dir_path]
```

Data Types

<i>fillview_name</i>	string
<i>layer_name</i>	string
<i>rectangle_list</i>	rectangle
<i>dir_path</i>	string

ARGUMENTS

-output_view *fillview_name*

Specifies the name of the output fill view. The default value is *cell_name.FILL*. The specified file will overwrite the existing fill view file. This option is mutually exclusive with **-purge**, **-eco**, and **-append**.

-purge

Removes metal fills in the default fill view of the current cell. Only fills in selected areas on selected layers would be removed. If neither **-select_layers** nor **-bounding_boxes** is specified, the whole FILL view would be removed. This option is mutually exclusive with **-output_view**, **-eco**, **-append**, **-mode**, and **-excluded_bounding_boxes**.

-eco

Specifies this option with the **-select_layers**, **-bounding_boxes**, or **-excluded_bounding_boxes** option for the purpose of post-ECO layer-based fill removal and refill. First, all existing metal fills in selected areas on selected layers are removed. Next, Hercules or IC Validator is called to refill those selected areas only. The metal fills outside selected areas or on other metal layers remain unchanged. Both removal and refill are operated on the default fill view of the current cell. This option is mutually exclusive with **-output_view**, **-purge**, and **-append**.

-append

Specifies not to modify existing metal fills in the output fill view. You can use this option to incrementally insert metal fills. By default, the new output fill view will overwrite the existing one. If you specify this option,

the new fills would be appended to the existing output view without modifying the existing data. This option is mutually exclusive with **-output_view**, **-purge**, and **-eco**.

-mode flat

Specifies the mode of fills that Hercules or IC Validator generates. There are two modes of fills: hierarchical fills and flattened fills. By default, the mode in the runset is used. If the runset writes hierarchical fills, you can use **flat** to convert them to flattened fills. This option is mutually exclusive with **-purge**.

-select_layers {layer_name}

Indicates a list of metal layers where the metal fills are inserted or removed. The names of layers must be the strings such as *m1*, *m2*, and so on. By default, **signoff_metal_fill** is performed on all metal routing layers that are defined by **set_ignored_layers** command, but you can fill any specific metal layers defined in the technology file using this option.

-bounding_boxes {rectangle_list}

Indicates a list of rectangle bounding boxes where metal fills are inserted or removed. Each rectangle is formed by two coordinates: {{*llx* *lly*} {*urx* *ury*}}, where *llx*, *lly*, *urx*, and *ury* are float values. The unitLength defined in the technology file is used. The selected regions are applied to all selected layers. By default, the working area is the entire chip. This option is mutually exclusive with **-excluded_bounding_boxes**.

-excluded_bounding_boxes {rectangle_list}

Indicates a list of rectangle bounding boxes where metal fills are NOT inserted or removed. Each rectangle is formed by two coordinates: {{*llx* *lly*} {*urx* *ury*}}, where *llx*, *lly*, *urx*, and *ury* are float values. The unitLength defined in the technology file is used. The excluded regions are applied to all selected layers. By default, the excluded area is none. This option is mutually exclusive with **-purge** and **-bounding_boxes**.

-run_dir *dir_path*

Specifies the path of working directory. The default is the **signoff_fill_run** directory under the current working directory. The path can be either relative or complete.

DESCRIPTION

This command invokes Hercules or IC Validator to perform metal fill on current cell to meet the metal density requirements and to perform post-ECO layer-based removal and refill. The output of this procedure is a fill view that consists of the fill-track objects and is stored in the FILL directory of the design Milkyway library. You should use this command on a fully routed DRC-clean or near DRC-clean design. The settings of Hercules or IC Validator environment are required and can be specified by using **set_physical_signoff_options** before running **signoff_metal_fill**. Note that distributed processing metal fill for IC Validator is not supported in this release, and thus all distributed processing related settings in **set_physical_signoff_options** are ignored.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example fills all empty regions with metal fills. The output library is the current design library, and the output fill view is *cell_name.FILL*. The output fill view will overwrite the original fill view.

```
prompt> signoff_metal_fill
```

The following example fills all empty regions with metal fills. The output fill view is "newFill.FILL".

```
prompt> signoff_metal_fill -output_view newFill
```

The following example fills all empty regions with flattened metal fills.

```
prompt> signoff_metal_fill -mode flat
```

The following example fills all empty regions on **metall1**, outside the region {{100 150} {300 200}}.

```
prompt> signoff_metal_fill -select_layers {m1} \
-excluded_bounding_boxes {{100 150} {300 200}}
```

The following example removes the default fill view of the current cell.

```
prompt> signoff_metal_fill -purge
```

The following example removes fills on layers **metall1** and **metall3** in the default fill view of the current cell.

```
prompt> signoff_metal_fill -purge -select_layers {m1 m3}
```

The following example removes all metal fills on **metall1** and **metall3**, and then refills those two metal layers. The existing metal fills on other metal layers remain unchanged.

```
prompt> signoff_metal_fill -eco -select_layers {m1 m3}
```

The following example fills all empty regions in {{100 150} {300 200}}, without overwriting the existing metal fills.

```
prompt> signoff_metal_fill -append -bounding_boxes {{100 150} {300 200}}
```

SEE ALSO

`insert_metal_filler(2)`
`set_physical_signoff_options(2)`
`report_physical_signoff_options(2)`

signoff_opt

Performs signoff ECO optimization.

SYNTAX

```
status signoff_opt
[-effort low | medium | high]
[-only_psyn]
[-no_design_rule | -only_design_rule | -only_hold_time]
[-xtalk_reduction | -only_xtalk_reduction]
[-full_extract | -full_analysis]
[-skip_initial_analysis]
[-num_iteration integer]
[-aocvm]
[-path_based_analysis]
[-update_rail_voltage]
[-variation]
[-ignore_design_readiness]
[-keep_license]
[-snapshot base_name]
```

ARGUMENTS

-effort low | medium | high

Specifies the effort level for **signoff_opt**. The default effort level is *medium*. If you specify *high*, **signoff_opt** spends more time to further improve the quality of results (QoR). If you specify *low*, **signoff_opt** spends less time on improving the quality of results (QoR).

-only_psyn

Performs optimization only. No incremental signoff analysis will be performed.

-no_design_rule | -only_design_rule | -only_hold_time

Specifies whether or not the tool fixes design rule/hold time violations before exiting.

-xtalk_reduction | -only_xtalk_reduction

Runs routing-based crosstalk reduction optimization in addition to signal integrity (SI) optimization. By default, this option is off.

-full_extract | -full_analysis

Performs full extraction with Star-RCXT. Use **-full_extract** with **-full_analysis**. Otherwise, the tool runs Star-RCXT with incremental extraction and creates a full netlist output. Use **-full_analysis** to perform full timing analysis with PrimeTime.

-skip_initial_analysis

Skips the initial signoff analysis. This option is valid only if you have performed **run_signoff** before **signoff_opt**.

```

-num_iteration integer
    Specifies the number of iterations to perform optimization and incremental
    signoff analysis. The default is 0, which lets the tool decide what is the
    appropriate number of iterations.

-aocvm
    Indicates that the timing paths are to be adjusted using Advanced On-Chip
    Variation Modeling (AOCVM) information. AOCVM computes the effects of OCV on
    timing using variable derate factors that consider the location and the logic
    depth of each path being analyzed. This approach reduces pessimism compared
    to global derating, thereby minimizing unnecessary over-design.

-path_based_analysis
    Enables path-based analysis capability in PrimeTime.

-update_rail_voltage
    Estimates and updates rail voltages for the changed cells. This switch is
    valid only with IR analysis flow.

-variation
    Indicates that Star-RCXT VX and PrimeTime VX are invoked to perform variation
    aware analysis.

-ignore_design_readiness
    Disables the design readiness check in signoff_opt.

-keep_license
    Prevents from releasing IC Compiler licenses when running signoff tools and
    the PrimeTtime licenses when running optimization.

-snapshot base_name
    Enables snapshot. signoff_opt saves a design after each optimization, using
    the given base_name, appended with an index. signoff_opt also saves a session
    from PrimeTime, using the given base_name, appended with an index.

```

DESCRIPTION

This command performs optimization based on signoff costing from signoff tools: PrimeTime and Star-RCXT. Star-RCXT provides signoff quality parasitic extraction, and PrimeTime provides signoff quality timing and SI analysis. IC Compiler uses the signoff costing from these tools to perform optimization on the design. Use **set_primate_options** and **set_starrcxt_options** to customize PrimeTime and Star-RCXT settings for the **signoff_opt** run.

It is recommended that the designs still need to go through regular timing/SI closure flows within IC Compiler to reduce the number of violations seen by signoff tools as much as possible. This is to reduce runtime of **signoff_opt** and to achieve best quality of results (QoR).

signoff_opt has a built-in readiness checker which checks the following conditions:

- The design shall have no more than 100 violating end points in either best case or worst case analysis.

- The design shall have no routing shorts.
- The number of routing design rule violations shall be no more than 0.1% of the number of nets or 100 (whichever is bigger).
- The number of logic design rule violations shall be no more than 0.1% of the number of nets or 100 (whichever is bigger).

If the design does not meet the design readiness check, you can still force **signoff_opt** to run signoff driven optimization. However, the design might not converge to a solution with better quality of results (QoR).

To enable SI fixing, use the **set_si_options** command. To enable hold time fixing, use the **set_hold_fix** command.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following example runs the **signoff_opt** command.

```
prompt> open_mw_cel -lib my_lib my_cel
prompt> set_primestime_options\
-exec_dir /PrimeTime/linux/syn/bin
prompt> set_starrcxt_options\
-exec_dir /StarRCXT/linux/bin\
-max_nxtgrd_file /design/max.nxtgrd\
-map_file /design/map_file
prompt> signoff_opt
prompt> save_mw_cel
```

```

size_cell

Relinks leaf cells to a new library cell that has the required drive strength (or other properties).

SYNTAX

```
collection size_cell
cell_object
lib_cell_object
```

Data Types

<i>cell_object</i>	list
<i>lib_cell_object</i>	string

ARGUMENTS

cell_object

Specifies the leaf cell to be relinked. Each cell must be in scope (at or below the current instance).

lib_cell_object

Specifies the library cell objects to which the specified cell is to be linked. In this case, each object is either a named library cell or a library cell collection. The library cells specified must be logical equivalent to the library cell which will be relinked.

DESCRIPTION

The **size_cell** command changes the drive strength (or other properties) of a leaf cell by relinking it to a new library cell that has the required properties. Like all other netlist editing commands, for **size_cell** to succeed, all of its arguments must succeed. If any arguments fail, the netlist remains unchanged. **size_cell** returns the collection of cells sized if successful and a NULL string if unsuccessful. Each cell in *cell_list* must be in scope; that is, at or below the current instance.

The *lib_cell* that is being swapped in must conform to the following restrictions:

- *lib_cell* must be functionally compatible with the current library cell to which the cells in *cell_list* are linked.
- *lib_cell* cannot be the same as the current library cell of any of the cells in *cell_list*.
- *lib_cell* must have the same pin count and pin directions as the current library cell of the cells in *cell_list*.

You can get a list of library cells that are compatible with a given cell using the **get_alternative_lib_cells** command.

The **size_cell** command is for leaf cells only. **size_cell** is optimized for incremental timing and does not cause a full timing update.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, an attempt to size a cell fails because the target is not functionally equivalent. After finding a compatible library cell, the second attempt succeeds.

```
prompt> size_cell o_reg1 class/NR4P
Error: Could not size 'o_reg1' ('FD2') with 'NR4P'. (NLE-009)

prompt> get_alternative_lib_cells o_reg1
{"class/FD2P"}

prompt> size_cell o_reg1 class/FD2P
Information: Sizing cell 'o_reg1' with lib cell 'class/FD2P'
{o_req1}
```

SEE ALSO

`get_alternative_lib_cells(2)`
`get_libs(2)`
`get_lib_cells(2)`

sizeof_collection

Returns the number of objects in a collection.

SYNTAX

```
int sizeof_collection  
collection1
```

Data Types

collection1 collection

ARGUMENTS

collection1

Specifies the collection for which to get the number of objects. If the empty collection (empty string) is used for the *collection1* argument, the command returns 0.

DESCRIPTION

The **sizeof_collection** command is an efficient mechanism for determining the number of objects in a collection.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows a simple way to find out how many objects matched a particular pattern and filter in a **get_cells** command.

```
prompt> echo "Number of hierarchical cells: \"\n  [sizeof_collection [get_cells * -hier] \"\n    -filter \"is_hierarchical == true\"]]"  
Number of hierarchical cells is: 10
```

The following example shows what happens when the argument to **sizeof_collection** results in an empty collection.

```
prompt> set s1 [get_cells *]  
{"u1", "u2", "u3"}  
prompt> set ssize [filter_collection $s1 "area < 0"]  
prompt> echo "Cells with area < 0: [sizeof_collection $ssize]"  
Cells with area < 0: 0  
prompt> unset s1
```

SEE ALSO

`collections(2)`
`filter_collection(2)`

`sizeof_collection`
2746

skew_opt

Optimizes clock skews to increase timing slack and writes the solution to an output file. By default, the output file is named "skew_opt.tcl" and is automatically sourced.

SYNTAX

```
status skew_opt
[-output file_name]
[-clock_balancing_only]
[-no_optimization]
[-no_auto_source]
[-fix_boundary_pins]
[-ignore_boundary_paths]
[-pins pin_list]
[-clocks clock_list]
[-path_groups path_group_list]
[-enable_pins]
[-macro_pins]
[-halfcycle_path_pins]
[-setup]
[-hold]
[-setup_margin setup_margin_value]
[-hold_margin hold_margin_value]
[-guard_band guard_band_value]
[-adjustment_limit adjustment_limit_value]
[-decrease_factor decrease_factor_value]
[-improvement_threshold improvement_threshold_value]
[-resolution resolution_value]
```

Data Types

<i>file_name</i>	string
<i>pin_list</i>	list of pins
<i>clock_list</i>	list of clocks
<i>path_group_list</i>	list of path-groups
<i>setup_margin_value</i>	float
<i>hold_margin_value</i>	float
<i>guard_band_value</i>	float
<i>adjustment_limit_value</i>	float
<i>decrease_factor_value</i>	float
<i>improvement_threshold_value</i>	float
<i>resolution_value</i>	float

ARGUMENTS

This group of options controls what **skew_opt** does with the solution file:

```
-output file_name
        Specify the name of the solution file. By default the name of the solution
        file is "skew_opt.tcl".
```

```
-clock_balancing_only
    Only configure inter-clock delay balancing groups; do not write any pin-specific annotations to the output file. This is useful to automatically configure inter-clock balancing without changing pin skews.

-no_optimization
    Do not optimize; write the solution file using the present clock network latencies. This option uses skew_opt to translate skews set by some other means to the clock-tree exceptions that will implement those skews. By default skew_opt will optimize the skews itself before writing the solution file.

-no_auto_source
    Do not automatically source the solution file. This option can be used to explore skew_opt improvements with different settings without applying the solution file. You can source the solution file manually when/if desired. By default skew_opt will source the solution file. See the OUTPUT section for more information about controlling how sections of the solution file are activated.
```

This group of options controls how **skew_opt** handles I/O paths:

```
-fix_boundary_pins
    Do not adjust latencies at the clock pins of registers participating in paths with I/O ports. This option allows external blocks to be designed without having to know the latency at each individual boundary register. This option also activates the -ignore_boundary_paths option below.

-ignore_boundary_paths
    Ignore paths to and from I/O ports. Allows latency adjustments on boundary registers to improve register-to-register paths without caring about the paths to and from I/O ports. This option can be useful if the external clock latencies for the I/O ports are unknown. To additionally prevent latency adjustments at boundary registers, use the -fix_boundary_pins option instead.
```

This group of options filters what **skew_opt** considers for optimization; when the options are used together, the intersection of their sets are used:

```
-pins pin_list
    Specify a list of clock pins to optimize skews for.

-clocks clock_list
    Specify a list of clocks to optimize skews for.

-path_groups path_group_list
    Specify a list of path-groups to optimize skews for.
```

This group of options selects what **skew_opt** considers for optimization; when the options are used together, the union of their sets are used; when a pin is selected for optimization by the option(s) from this group, all the timing paths connected to the pin are used in optimization:

```
-enable_pins
    Only adjust those clock pins that participate as startpoints in enable-timing paths to clock-gating endpoints.
```

```

-macro_pins
    Only adjust clock pins on macro cells.

-halfcycle_path_pins
    Only adjust clock pins that participate in paths where the startpoint and
    endpoint have opposing edge directions.

```

This group of options selects what type of timing constraints to consider, and how much margin to subtract from the slacks to coerce **skew_opt** to improve timing for paths that meet timing by a small amount:

```

-setup
    Collect setup constraints. By default only setup constraints are collected,
    so specifying -setup by itself is unnecessary.

-hold
    Collect hold constraints. By default this is not performed. This option can
    be specified with or without -setup. See the DETAILS section for more
    information about using hold constraints with skew_opt.

-setup_margin setup_margin_value
    Subtract this value (in nanoseconds) from the collected setup slacks before
    launching skew optimization. A positive value can be used to coerce skew_opt
    to create additional setup slack for paths that are only slightly non-
    violating. The default value is 0.

-hold_margin hold_margin_value
    Subtract this value (in nanoseconds) from the collected hold slacks before
    launching skew optimization. A positive value can be used to coerce skew_opt
    to create additional hold slack for paths that are only slightly non-
    violating. The default value is 0.

```

This group of options controls the adjustments **skew_opt** makes:

```

-guard_band guard_band_value
    Specify a positive slack threshold (in nanoseconds) for clock pins above
    which can be consumed to improve the worst/total negative slack for the
    design. This can be used to reduce an increase in the number of violating
    paths at the expense of less timing improvement. The default value is 0, which
    means that a guard-band is not used (not that positive slacks are kept at or
    above zero). To keep positive slacks at or above zero, use a tiny positive
    value (e.g. 0.001).

-adjustment_limit adjustment_limit_value
    Specify a limit on skew adjustments (in nanoseconds). Changes in clock
    network latency, either increases or decreases, will be constrained by this
    amount. Changes are also constrained by the clock period, and decreases have
    an additional constraint controlled by the -decrease_factor option. The
    default value of 1e+30 essentially shuts this feature off.

-decrease_factor decrease_factor_value
    Specify a fractional limit on skew decreases using a value between zero and
    one. The minimum latency allowed will be the larger of: zero, the initial
    latency minus the adjustment limit, the initial latency minus the clock
    period, and the initial latency multiplied by one minus the decrease factor.

```

The default decrease factor is 0.5, meaning that latencies will be allowed to decrease up to 50% of their initial value. It is easier for clock tree synthesis to increase latencies than to decrease them, and a zero latency is not physically realizeable. Some highly customized flows require an increase-only solution, in which case a decrease factor of 0 may be used. For designs with many clock-tree levels, a larger decrease factor may yield more slack improvement.

-improvement_threshold *improvement_threshold_value*

Specify the threshold (in nanoseconds) that **skew_opt** must improve the worst negative slack (WNS) by in order to create a solution file. If **skew_opt** cannot meet this threshold, an empty solution file will be created. If both -setup and -hold are specified, the combined WNS improvement will be compared against the improvement threshold. The default value is 0.010 (10ps).

-resolution *resolution_value*

Snap the clock-tree exception values to an integer multiple of this value (in nanoseconds). The default value is 1e-3 (1ps), and the minimum value allowed is 1e-4. Some highly customized flows require the clock-tree exceptions to be an integer multiple of some specific delay value.

DESCRIPTION

The **skew_opt** command does the following by default:

- Collects the worst timing path between every startpoint/endpoint pair.
- Collects the clock latencies at every startpoint/endpoint.
- Classifies each pin as adjustable, fragile, or fixed.
- Optimizes the latencies at adjustable pins to improve timing slacks.
- Converts the latencies to skews for clock-tree synthesis to implement.
- Configures inter-clock balancing for clock-tree synthesis.
- Writes a solution file.
- Sources the solution file.

The following options control what happens with the solution file:

-output **-clock_balancing_only** **-no_optimization** **-no_auto_source**

The following options control how I/O paths and pins are handled:

```
-fix_boundary_pins -ignore_boundary_paths
```

The following options control which pins and paths are considered:

```
-pins -clocks -path_groups -enable_pins -macro_pins -halfcycle_path_pins
```

The following options control how types and values of timing constraints are considered:

```
-setup -hold -setup_margin -hold_margin
```

The following options control the skew adjustments:

```
-guard_band -adjustment_limit -decrease_factor -improvement_threshold -resolution
```

Each of the above options is described in detail at the top of this man page in the ARGUMENTS section.

FLOW

The **skew_opt** command is intended to be used within a two-pass clock tree synthesis flow. The first pass produces realistic skews and slacks for **skew_opt** to improve upon, and the second pass implements the **skew_opt** solution. By using two passes, reliable improvements can be made to I/O paths and paths to clock-gating cells. Additionally, most of the changes **skew_opt** makes can be implemented in the second pass with new clustering and leveling, instead of adding many clock-tree buffers.

Here is the basic recommended flow:

```
place_opt save_mw_cel -as placed close_mw_cel
```

```
open_mw_cel placed skew_opt -clock_balancing_only clock_opt -inter_clock_balance  
skew_opt close_mw_cel
```

```
open_mw_cel placed source skew_opt.tcl clock_opt -inter_clock_balance route_opt
```

If **update_clock_latency** is to be used to change the ideal latencies for I/O ports, this is the recommended flow:

```
place_opt save_mw_cel -as placed close_mw_cel
```

```
open_mw_cel placed set_latency_adjustment_options ... skew_opt -clock_balancing_only  
clock_opt -inter_clock_balance -update_clock_latency -no_clock_route route_group -  
all_clock_nets extract_rc skew_opt close_mw_cel
```

```
open_mw_cel placed source skew_opt.tcl clock_opt -inter_clock_balance -  
no_clock_route route_group -all_clock_nets extract_rc route_opt
```

The above example separates clock-routing from **clock_opt** in order to avoid having a second **update_clock_latency** called after the internal clock-routing. This ensures **skew_opt** will see the same I/O latencies as **psynopt** does, which makes the flow more reliable.

PLEASE NOTE: It is imperative that **update_clock_latency** not be run after the

solution file is sourced, otherwise the solution will be unrealized.

OUTPUT

The changes are written to an output file, also referred to as the "solution file", which contains three types of settings:

```
command group controlling variable -----
----- set_clock_latency skew_opt_skip_ideal_clocks set_clock_tree_exceptions
skew_opt_skip_propagated_clocks set_inter_clock_delay_options
skew_opt_skip_clock_balancing
```

Each type of command is grouped together and is applied only when the associated controlling variable is either *false* or undefined. Note that the controlling variables only affect which pieces of the solution file are active, not any behavior of the **skew_opt** command itself. The command types are used as follows.

A first set of **set_clock_latency** commands is used to capture the ideal latencies on clock objects used to clock ports at the time **skew_opt** is run; these commonly come from the **update_clock_latency command**, but they can also come from a SDC file loaded earlier in the design flow.

A second set of **set_clock_latency** commands is used to capture the ideal latencies on pins in order to allow users to see an estimate of the timing improvement before the second pass through **clock_opt**. Note that this estimate is only accurate immediately after **skew_opt** is run after the first pass through **clock_opt**; this is because there will be realistic latencies at clock-gating cells and realistic slews to select setup and hold times.

PLEASE NOTE: Timing reports may not be accurate after sourcing the solution file ahead of the second pass through **clock_opt**. This is because the **skew_opt** solution is in response to the propagated clock tree state.

PLEASE NOTE: The variable **skew_opt_skip_ideal_clocks** should not be set true before sourcing the solution file ahead of the second pass through **clock_opt**; otherwise, the I/O latencies will likely be very different between the passes, and timing improvement will likely not occur.

Next a set of **set_clock_tree_exceptions** commands are provided to configure clock tree synthesis to implement the optimized skews. These are rise/fall specific float-pin exceptions.

Lastly, a set of **set_inter_clock_delay_options** commands is provided to configure clock tree synthesis to balance clocks that relate through timing paths.

DETAILS

Hold constraints are not collected by default because we assume **skew_opt** will be used primarily in a pre-route flow. Before steps like scan-chain ordering, CTS, and routing are performed, hold slacks are not known with enough predictability to be useful to guide the skew optimization. To minimize the impact on hold violations, however, **skew_opt** will post-process the solution found for the best setup WNS so that it is most favorable for hold WNS without worsening the setup WNS. If it is

desired to test what would happen if hold constraints are considered, we provide the -hold option to **skew_opt**.

During optimization **skew_opt** reports the worst negative slack (WNS) and cumulative negative slack (CNS) for the pins being adjusted. CNS is different from total negative slack (TNS); TNS is the sum of the WNS at every endpoint, whereas CNS is the sum of the WNS between every startpoint/endpoint pair.

After optimization **skew_opt** may show one of the following messages:

"There are dangling paths in this design." "There are floating clock-pins in this design." "There are clocks shared by data ports and sink pins in this design."

These messages are for informational purposes only and require no action. Dangling paths involve registers that are exclusively either a startpoint or an endpoint; designs with dangling paths require more processing than designs without them. Floating clock-pins occur at registers that only have paths to and from themselves; these cannot be optimized. When clocks are shared by data ports and sink pins in a design, the ports are clocked by an ideal clock latency value, not a propagated one; virtual-clocks can be used to make this more clear if desired.

Pre-existing exclude exceptions set with the **set_clock_tree_exceptions** command are honored by **skew_opt**; no adjustments are made to those pins.

The conversion of latencies to skews is different depending upon whether a subset option (i.e. -pins, -clocks, -path_groups, etc.) is in effect. When the default behavior is used to write clock tree exceptions for all sinks, this formula is used:

```
float_pin_value = minimum_desired_latency - desired_latency
```

where `minimum_desired_latency` is the `minimum_desired_latency` over all pins. This has the effect of creating only non-positive float-pin values, which yields the best skew correlation from clock tree synthesis. If a master clock domain has source latency, it will be included in the above conversion.

If a subset option is in use, however, this formula is used:

```
float_pin_value = initial_latency - desired_latency
```

where `initial_latency` is the value before **skew_opt** is run.

LIMITATIONS

Note that the following types of paths fundamentally cannot be improved by adjusting skew:

```
-- feedthrough paths -- looping paths from a register to itself
```

Additionally, clock tree synthesis has the limitation that paths to or from pins in the middle of clock trees (e.g. clock-gating cells) cannot be adjusted by **set_clock_tree_exceptions** commands. This is because placing a float-pin exception on a nonstop-pin will convert that pin to a stop-pin. Hence **skew_opt** will not optimize latencies at clock-gating cells.

Similarly, clock tree synthesis cannot separately shift the phase of clock pins within an interface logic model (ILM), so **skew_opt** will not optimize latencies within ILM's.

Since the slack at level-sensitive latches is not a simple function of the clock network latency, **skew_opt** presently does not optimize latencies at level-sensitive latches, nor the edge-triggered registers that connect directly to and from them.

The following "fragile" clock pins are written to the solution file even though **skew_opt** did not optimize them; this is done to preserve their skew in the context of those pins **skew_opt** did optimize:

```
-- ILM clock pins -- unconstrained clock pins -- level-sensitive latch clock pins --
clock pins at registers connecting to/from latches
```

The inclusion of the above pins is affected by the various subset options (e.g. -pins, -clocks, -path_groups, etc.). Unclocked sink pins get exclude exceptions instead of float-pin exceptions.

skew_opt will improve the slack for the paths it can adjust skews for, but if those paths do not include the critical paths, the **report_qor** command may not show the WNS improvement claimed by **skew_opt**.

Users can create a separate path-group for feedthrough paths:

```
group_path -from [all_inputs] -to [all_outputs] -name FEEDTHROUGH
```

skew_opt does not adjust skews to satisfy **set_min_delay** or **set_max_delay** constraints; the **report_qor** command may show negative slack due to those constraints even though the skew-dependent slack has improved.

Typically the set of pins affected by the **skew_opt** output file should match that shown by the **report_clock_timing** latency report; however, **report_clock_timing** also shows clock pins on unconstrained paths which **skew_opt** ignores.

Presently **skew_opt** does not consider clock-tree exceptions placed on combinational pins. It is possible that manually placed clock-tree exceptions will interfere with those created by **skew_opt**; the **check_clock_tree** command can be used to check for such issues.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

If **skew_opt** is run with no options, skews on all clock pins are adjusted to maximize setup slack, and the output file *skew_opt.tcl* is created and sourced:

```
prompt> skew_opt
```

A user can restrict the pins adjusted by **skew_opt** by using the **-pins** option:

```
prompt> skew_opt -pins [get_pins "prefix/*/clk"]
```

A user can restrict the path-groups adjusted by **skew_opt** by using the **-path_groups** option:

```
prompt> skew_opt -path_groups [get_path_groups "prefix/*"]
```

A user can restrict the sourcing of the output file to not apply the **set_inter_clock_delay_options** commands by doing this:

```
prompt> set skew_opt_skip_clock_balancing true  
prompt> skew_opt
```

slot_wire

Slots wide wires and contact arrays on selected nets by replacing them with thinner wires and smaller arrays.

SYNTAX

```
integer slot_wire
-nets {collection_of_nets}
[-signal_net]
[-cutwidth {layer distance list}]
[-cutlength {layer distance list}]
[-width {layer distance list}]
[-length {layer distance list}]
[-sidespace {layer distance list}]
[-endspace {layer distance list}]
[-sideclearance {layer distance list}]
[-endclearance {layer distance list}]
[-no_stagger {layer list}]
[-dmode {layer list}]

```

Data Types

<i>collection_of_nets</i>	collection
<i>file_name</i>	string

ARGUMENTS

```
-nets {collection_of_nets}
      Specifies the nets to slot wires on. If you specify more than one net in a
      collection they must be separated by a space. This option is required.

-signal_net
      Allows the slotter to work on signal nets as well as preroute wires. By
      default, the command considers preroute wires only.

-cutwidth {layer distance list}
      Specifies wire width threshold to slot. The parameter is a list of layer and
      wire width threshold values. The <layer> can be specified as either the
      layerNumber or maskName from the technology file. There is one predefined
      name to indicate that the following value will apply to all layers, rather
      than a particular layer. It is all_layers. Names and values in a list should
      be separated by space. The default is set to the value of the SlotRule
      widthThreshold, when SlotRule is defined for a layer in the technology file,
      or 99, if not defined.
```

-cutlength {layer distance list}
 Specifies wire length threshold to slot. The parameter is a list of layer and wire length threshold values. The <layer> can be specified as either the layerNumber or maskName from the technology file. There is one predefined name to indicate that the following value will apply to all layers, rather than a particular layer. It is *all_layers*. Names and values in a list should be separated by space. The default is set to the value of the SlotRule lengthThreshold, when SlotRule is defined for a layer in the technology file, or 99, if not defined.

-width {layer distance list}
 Specifies open slot width. The parameter is a list of layer and open slot width values. The <layer> can be specified as either the layerNumber or maskName from the technology file. There is one predefined name to indicate that the following value will apply to all layers, rather than a particular layer. It is *all_layers*. Names and values in a list should be separated by space. <distance> must be within the range of the minSlotWidth and maxSlotWidth, when the SlotRule is defined for a layer in the technology file. The default is set to the value of the SlotRule minSlotWidth, when SlotRule is defined for a layer in the technology file, or minSpace, if not defined.

-length {layer distance list}
 Specifies the open slot length. The parameter is a list of layer and open slot length values. The <layer> can be specified as either the layerNumber or maskName from the technology file. There is one predefined name to indicate that the following value will apply to all layers, rather than a particular layer. It is *all_layers*. Names and values in a list should be separated by space. <distance> must be within the range of the minSlotLength and maxSlotLength, when the SlotRule is defined for a layer in the technology file. The default is set to the value of the SlotRule maxSlotLength, when SlotRule is defined for a layer in the technology file, or 10*minSpace, if not defined.

-sidespace {layer distance list}
 Specifies the spacing between the sides of two adjacent parallel open slots. The parameter is a list of layer and sidespace values. The <layer> can be specified as either the layerNumber or maskName from the technology file. There is one predefined name to indicate that the following value will apply to all layers, rather than a particular layer. It is *all_layers*. Names and values in a list should be separated by space. <distance> must be within the range of the minSideSpace and maxSideSpace, when the SlotRule is defined for a layer in the technology file. The default is set to the value of the SlotRule maxSideSpace, when SlotRule is defined for a layer in the technology file, or 10*minWidth, if not defined.

-endspace {layer distance list}
 Specifies the spacing between the ends of two consecutive open slots. The parameter is a list of layer and endspace values. The <layer> can be specified as either the layerNumber or maskName from the technology file. There is one predefined name to indicate that the following value will apply to all layers, rather than a particular layer. It is *all_layers*. Names and values in a list should be separated by space. <distance> must be within the range of the minEndSpace and maxEndSpace, when the SlotRule is defined for a layer in the technology file. The default is set to the value of the SlotRule maxEndSpace, when SlotRule is defined for a layer in the technology file, or 10*minWidth,

if not defined.

-sideclearance {layer distance list}

Specifies the spacing from the out-most slot to the side-edge of the slotting wire. The parameter is a list of layer and sideclearance values. The <layer> can be specified as either the layerNumber or maskName from the technology file. There is one predefined name to indicate that the following value will apply to all layers, rather than a particular layer. It is *all_layers*. Names and values in a list should be separated by space. <distance> must be within the range of the minSideClearance and maxSideClearance, when the SlotRule is defined for a layer in the technology file. The default is set to the value of the SlotRule maxSideClearance, when SlotRule is defined for a layer in the technology file, or 10*minWidth, if not defined.

-endclearance {layer distance list}

Specifies the space from the out-most slot to the end-edge of the slotting wire. The parameter is a list of layer and endclearance values. The <layer> can be specified as either the layerNumber or maskName from the technology file. There is one predefined name to indicate that the following value will apply to all layers, rather than a particular layer. It is *all_layers*. Names and values in a list should be separated by space. <distance> must be within the range of the minEndClearance and maxEndClearance, when the SlotRule is defined for a layer in the technology file. The default is set to the value of the SlotRule maxEndClearance, when SlotRule is defined for a layer in the technology file, or 10*minWidth, if not defined.

-no_stagger {layer list}

Specifies not to stagger slots. The parameter is a list of layer(s). The <layer> can be specified as either the layerNumber or maskName from the technology file. There is one predefined name to indicate that the option will apply to all layers, rather than a particular layer. It is *all_layers*. Names in a list should be separated by space. The default is set to allow slot staggering.

-dmode {layer list}

Enables the dimension rule mode. In this mode, slotting must meet the following dimension rule constraints: It must create the number of slot rows as $n = \text{wire_width}/\text{cutWidth}$. It must center the rows at multiples of $\text{wire_width}/(n+1)$. The command issues a warning if, using these constraints, it cannot find a valid slotting solution for a particular wire. The parameter is a list of layer(s). The <layer> can be specified as either the layerNumber or maskName from the technology file. There is one predefined name to indicate that the option will apply to all layers, rather than a particular layer. It is *all_layers*. Names in a list should be separated by space. The default is a disabled dimension rule mode.

-treat_width_as_max

Sets the specified slot width to the maximum. This means that the open slot width might be adjusted to smaller values to fit some wide wires when necessary, but no less than the value of the minSlotWidth, when defined in the technology file. The default is to set the specified slot width to the minimum, allowing open slot width to be adjusted to larger values to fit some wide wires when necessary, but no larger than the value of the maxSlotWidth, when defined in the technology file.

-treat_length_as_min
Sets the specified slot length to the minimum. This means that the open slot length might be adjusted to larger values to fit some wide wires when necessary, but no larger than the value of the maxSlotLength, when defined in the technology file. The default is to set the specified slot length to the maximum, allowing open slot length to be adjusted to smaller values to fit some wide wires when necessary, but no less than the value of the minSlotLength, when defined in the technology file.

-treat_space_clearance_min
Treats sideSpace, endSpace, sideClearance and endClearance as minimum. The actual parameters might be adjusted to larger values, but should be less than the respective maximum values when defined in the technology file. The default is to treat them as maximum. In this case the actual parameters might be adjusted to smaller values, but should be no less than the respective minimum values when defined in the technology file.

-min_via_removal
Minimizes the removal of existing vias on a slotted wire. The default is not to minimize.

-recreate_vias
Recreates vias on slotted wires in the original via area only. When not selected, vias can be recreated in the entire intersection area of the connecting wires.

-report
Prints out more slotting information for each wire. The default is not to print.

-report_wire_relationship *file_name*
Prints out the bounding box of each slotted parent wire and its child wires to a named output file. The default is not to output.

-undo
Restores slotted wires to the shape before last **slot_wire** run.

DESCRIPTION

Slots wide wires and contact arrays on selected nets by replacing them with thinner wires and smaller arrays.

You can change the internal application of DRC rules by using the **set_preroute_drc_strategy** command.

Slotting rules might be defined in a technology file, where each layer has its own rule in the format, shown in the following example:

```
SlotRule "" {layerNumber = 18 lengthThreshold = 20 widthThreshold = 10 minSlotWidth
= 1 maxSlotWidth = 2 minSlotLength = 8 maxSlotLength = 16 minSideSpace = 1
maxSideSpace = 5 minSideClearance = 1 maxSideClearance = 5 minEndSpace = 1
maxEndSpace = 2 minEndClearance = 1 maxEndClearance = 2 }
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example slots wires of nets VDD and VSS, with wire width threshold of 10.0, length threshold of 20.0, open slot width of 5.0, open slot length of 10.0, applied to all layers:

```
prompt> slot_wire -nets {VDD VSS} \
-cutwidth {all_layers 10} \
-cutlength {all_layers 20} \
-width {all_layers 5} \
-length {all_layers 10}
```

The following example slots wires of nets VDD and VSS, with wire width threshold of 10.0, length threshold of 20.0, open slot width of 5.0, open slot length of 10.0, applied to METAL2 layer; width threshold of 8.0, length threshold of 30.0, open slot width of 2.0, open slot length of 5.0, applied to METAL3 layer:

```
prompt> slot_wire -nets {VDD VSS} \
-cutwidth {METAL2 10 METAL3 8} \
-cutlength {METAL2 20 METAL3 30} \
-width {METAL2 5 METAL3 2} \
-length {METAL2 10 METAL3 5}
```

SEE ALSO

`set_preroute_drc_strategy(2)`

snap_objects

Snaps objects to the default snap type. An object is snapped onto the nearest position that satisfies the snapping constraint.

SYNTAX

```
status snap_objects
[-snap_pin_to_edge]
objects
```

ARGUMENTS

-snap_pin_to_edge

Snaps terminals and soft macro pins to the closest relevant boundary.

This option causes a terminal to snap to the closest cell boundary, if it is not already on a cell boundary. A soft macro pin will be also snapped to the closest edge of the soft macro to which it belongs, if it is not already on a valid soft macro edge.

This option does not do anything if no terminals or soft macro pins are among the arguments.

objects

Argument is a collection of movable objects.

DESCRIPTION

Snap objects to the default snap types according to the object types of individual arguments.

The default snap type can be found with `get_object_snap_type`. It can also be set with `set_object_snap_type`. Except for snapping pins (soft macro pins or top-level pins) onto wire tracks, there is no built-in interaction with any part of the legalization code. When soft macro or top-level pins are snapped to wire tracks, care is taken to avoid shorts with other pins or wires, if at all possible. Furthermore, pins will not be snapped to wire tracks beyond the end point of a soft macro (or cell) edge.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example snaps pin "abc" to the nearest wire track if the pins are not already on a wire track. The pin will also be centered on the wire track.

```
prompt> get_object_snap_type -type pin
wiretrack
prompt> snap_objects [get_pins "abc"]
```

In following example the standard cell "abc" is first snapped to the minimum grid and then to the nearest cell row.

```
prompt> get_object_snap_type -type cell  
litho  
prompt> snap_objects [get_cells "abc"]  
prompt> set_object_snap_type -type cell -snap row  
litho  
prompt> get_object_snap_type -type cell  
row  
prompt> snap_objects [get_cells "abc"]
```

SEE ALSO

`set_object_snap_type(2)`
`get_object_snap_type(2)`
`set_user_grid(2)`

sort_collection

Sorts a collection based on one or more attributes, resulting in a new, sorted collection. The sort is ascending by default.

SYNTAX

```
collection sort_collection
[-descending] collection1 criteria
```

Data Types

<i>collection1</i>	collection
<i>criteria</i>	list

ARGUMENTS

<i>-descending</i>	Indicates that the collection is to be sorted in reverse order. By default, the sort proceeds in ascending order.
<i>collection1</i>	Specifies the collection to be sorted.
<i>criteria</i>	Specifies a list of one or more application or user-defined attributes to use as sort keys.

DESCRIPTION

You can use **sort_collection** to order the objects in a collection based on one or more attributes. For example, to get a collection of leaf cells increasing alphabetically, followed by hierarchical cells increasing alphabetically, sort the collection of cells using the **is_hierarchical** and **full_name** attributes as *criteria*.

In an ascending sort, Boolean attributes are sorted with those objects first that have the attribute set to *false*, followed by the objects that have the attribute set to *true*. In the case of a sparse attribute, objects that have the attribute come first, followed by the objects that do not have the attribute.

Sorts are ascending by default. The **-descending** option reverses the order of the objects.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sorts a collection of cells based on hierarchy, and adds a

second key to list them alphabetically. In this example, cells i1 and i2 are hierarchical, and o1 and o2 are leaf cells. Because **is_hierarchical** is a Boolean attribute, those objects with the attribute set to **false** are listed first in the sorted collection.

```
prompt> set zcells [get_cells {o2 i2 o1 i1}]
{"o1", "i2", "o1", "i1"}
prompt> set zsort [sort_collection $zc {is_hierarchical full_name}]
{"o1", "o2", "i1", "i2"}
```

SEE ALSO

[collections\(2\)](#)

sort_fp_pins

Sorts the specified collection of pins into alphabetic order by name or in reverse alphabetic order if -reverse is specified.

SYNTAX

```
status sort_fp_pins
[-reverse]

```

ARGUMENTS

```
-reverse
    reverse sort

pins
    collection of pins
```

DESCRIPTION

Sorts the specified collection of pins into alphabetic order by name or in reverse alphabetic order if -reverse is specified.

Note: supplied pins must belong to a single soft macro

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

Sort matching pins in reverse order:

```
> sort_fp_pins [get_pins -filter "is_hierarchical==true" *clk*]
```

SEE ALSO

`create_fp_pins(2)`

source

Read a file and evaluate it as a Tcl script.

SYNTAX

```
string source
[-echo] [-verbose] [-continue_on_error] file
```

Data Types

file string

ARGUMENTS

-echo

Echoes each command as it is executed. Note that this option is a non-standard extension to Tcl.

-verbose

Displays the result of each command executed. Note that error messages are displayed regardless. Also note that this option is a non-standard extension to Tcl.

-continue_on_error

Don't stop script on errors. Similar to setting the shell variable `sh_continue_on_error` to true, but only applies to this particular script.

file

Script file to read.

DESCRIPTION

The **source** command takes the contents of the specified *file* and passes it to the command interpreter as a text script. The result of the source command is the result of the last command executed from the file. If an error occurs in evaluating the contents of the script, then the **source** command returns that error. If a return command is invoked from within the file, the remainder of the file is skipped and the source command returns normally with the result from the return command.

By default, source works quietly, like UNIX. It is possible to get various other intermediate information from the source command using the **-echo** and **-verbose** options. The **-echo** option echoes each command as it appears in the script. The **-verbose** option echoes the result of each command after execution.

NOTE: To emulate the behavior of the dc_shell **include** command, use both of these options.

The file name can be a fully expanded file name and can begin with a tilde. Under normal circumstances, the file is searched for based only on what you typed. However, if the system variable `sh_source_uses_search_path` is set to "true", the file is searched for based on the path established with the `search_path` variable.

The **source** command supports several file formats. The *file* can be a simple ascii script file, an ascii script file compressed with gzip, or a Tcl bytecode script, created by TclPro Compiler. The **-echo** and **-verbose** options are ignored for gzip formatted files.

EXAMPLES

This example reads in a script of aliases:

```
prompt> source -echo aliases.tcl
alias q quit
alias hv {help -verbose}
alias include {source -echo -verbose}
prompt>
```

[sh_continue_on_error\(3\)](#)

split_clock_gates

Replicates (splits) integrated clock-gating cells that have timing violations on the enable pin.

SYNTAX

```
status split_clock_gates
```

ARGUMENTS

The **split_clock_gates** command has no arguments.

DESCRIPTION

For a placed design, **split_clock_gates** automatically replicates (splits) certain integrated clock-gating cells (ICGs). When running the command on a design that the clock trees have already been synthesized, the tool exits with the CTS-680 error message.

The ICGs to be replicated must meet the following two requirements:

1. The ICG has a timing violation on the enable pin.
2. The ICG drives a large enough fanout that it requires at least one level of clock buffers between the ICG and the registers that are driven by the ICG. This is determined by internal synthesis of the clock trees in the design.

When the requirements are met, the command replicates the ICGs by invoking the **split_clock_net** command automatically. At the end of **split_clock_net**, all clock trees will be removed.

ICGs that have the `is_fixed` attribute will not be replicated. If you want to replicate such ICGs that have timing violations, you should remove the `is_fixed` attribute before running **split_clock_gates**.

This command determines the enable pin of the ICGs based on the library attribute `clock_gate_enable_pin`. If the `split_based_on_test_pin` variable is set to true, the tool checks the timing on the test pin, instead of the enable pin, of the ICGs.

EXAMPLES

The following example replicates the violating clock-gating cells that do not have the `size_only` attribute.

```
prompt> set_split_clock_gates_options -honor_size_only
prompt> split_clock_gates
```

SEE ALSO

`split_clock_net(2)`

```
set_split_clock_gates_options(2)
reset_split_clock_gates_options(2)
report_split_clock_gates_options(2)
optimize_pre_cts_power(2)
```

split_clock_net

Duplicates the gates on the clock nets.

SYNTAX

```
status split_clock_net
[-objects net_or_gate_list]
[-gate_sizing]
[-gate_relocation]
[-split_any_cell_type]
[-split_intermediate_level_clock_gates]
[-operating_condition min | max | min_max]
[-isolate_float_pins]
[-drive_ungated_registers]
[-estimated_early_delay float]
```

Data Types

net_or_gate_list list

ARGUMENTS

```
-objects net_or_gate_list
    Duplicates the clock gates that you specify in the list. When you specify a
    net name, all the clock gates on that net are duplicated. Integrated clock-
    gating cells are duplicated by default.

-gate_sizing
    Sizes clock gates.

-gate_relocation
    Switches off gate relocation.

-split_any_cell_type
    Splits any gates of cell type.

-split_intermediate_level_clock_gates
    Splits intermediate-level clock gates.

-operating_condition [min | max | min_max]
    Instructs the clock tree synthesis engine to use the specified operating
    condition. The default is max.

-isolate_float_pins
    Isolates float pins from the other pins while duplicating the clock gates.

-drive_ungated_registers
    Adds a buffer to drive ungated registers.
```

DESCRIPTION

This command duplicates the clock gates you specify. If a list of nets is provided, all the clock gates on the given nets are duplicated. The command supports the duplication of integrated clock-gating cells by default. If the **cts_split_any_gate** variable is set to true, all clock gate duplication is enabled. Using the variable is equivalent to using the **-split_any_cell_type** option. If the **cts_split_intermediate_level_clock_gates** variable is set to true, the intermediate level of clock gates duplication is enabled. Using the variable is equivalent to using the **-split_intermediate_level_clock_gates** option. You can use the **-isolate_float_pins** option to separate float pins from the other pins.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example duplicates and resizes all the clock gates on net1 and net2.

```
prompt> split_clock_net -objects {net1 net2} -gate_sizing
```

SEE ALSO

`compile_clock_tree(2)`

split_mw_lib

Splits the top-level Milkyway design into different libraries. Splitting the library hierarchically facilitates concurrent design.

SYNTAX

```
status split_mw_lib
[-check_only]
[-to_dir path]
[-lib_prefix prefix]
-from_library mw_lib
mw_top_design
```

Data Types

<i>path</i>	string
<i>prefix</i>	string
<i>mw_lib</i>	string

ARGUMENTS

-check_only
Prints out the list of Milkyway designs, views, and versions but does not copy information to the destination library.

-to_dir *path*
The destination path of the new libraries. This path can be given as an absolute path or as a relative path. Relative paths will be resolved relative to the location of the library specified by **-from_library**. If this option is not given, the new libraries will be created at the same level as the given design library.

-lib_prefix *prefix*
This sets the prefix of the new libraries that are created. The name of the new libraries being created is determined by appending the *prefix* with *design_name*. If this option is not used, the default prefix "lib_" is used.

-from_library *mw_lib*
Specifies the name of the design library that contains the top-level Milkyway design that you want to split.

mw_top_design
Specifies the name of the top-level Milkyway design that you want to split.

DESCRIPTION

This command creates new design libraries in the directory specified by the **-to_dir** option. Each new library contains a single Milkyway design. The name of the new design libraries are determined by appending the *prefix* with the *design_name*. If the **-lib_prefix** option is not specified, the default prefix "lib_" is used. If the top-level Milkyway design contains a subdesign that is not a soft macro, such as a hard

macro or a standard design that is located in the design library, these subdesigns are copied to the destination design library containing the top-level design to maintain the original top-level design structure. No other Milkyway designs from the reference library are copied to the top-level design library.

All new libraries inherit the library information from the original library, including the technology file and reference library path.

After splitting, the new Milkyway designs include all information from the original Milkyway designs. Therefore, after splitting, you can perform block-level design concurrently on the resultant libraries.

After splitting, the new Milkyway designs have their versions set to 1.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example splits the chip_top design and its subdesigns from the myDesign design library to new design libraries.

```
prompt> split_mw_lib -check_only -from_library myDesign \
      chip_top
```

Library Files will be copied:
From: /Training/myDesign
To: /Training/lib_chip_top

Cells will be copied:
From: /Training/myDesign
To: /Training/lib_chip_top

cell: chip_top.CEL;2

Library Files will be copied
From: /Training/myDesign
To: /Training/lib_nand_macro

Cells will be copied:
From: /Training/myDesign
To: /Training/lib_nand_macro

cell: nand_macro.FRAM;2
cell: nand_macro.CEL;1

1

SEE ALSO

`copy_mw_cel(2)`
`save_mw_cel(2)`

split_net

Splits routing objects on one net into many other nets.

SYNTAX

```
status split_net
-start | list_of_nets | -batch
[-cells cell_list]
```

Data Types

list_of_nets list

ARGUMENTS

-start
Clears the generated files split_net_batch.tcl and split_net_batch. The **-batch**, **list_of_nets**, and **-start** options are mutually exclusive: you can use only one.

list_of_nets
Specifies that the routing on the first specified net should be split over the remaining nets in the list. This option is used in the generated split_net_batch.tcl file. The **-batch**, **list_of_nets**, and **-start** options are mutually exclusive: you can use only one. This option can only be used in conjunction with **-cells** option.

-batch
Splits the routing on the original nets when you use it after a sequence of **insert_buffer -on_route -repeater_distance** commands. The **-batch**, **Ilist_of_nets**, and **-start** options are mutually exclusive: you can use only one.

-cells *cell_list*
Specifies the cells where the routes needs to be broken which is now connected to the nets for which the routes are distributed This option is used in the generated split_net_batch.tcl file. This option can only be used in conjunction with **list_of_nets** option.

DESCRIPTION

This command re-uses the routing that was on a net before it was buffered by the execution of the **insert_buffer -on_route -repeater_distance** or **insert_buffer -on_route -divide_load_by** command.

The design must be routed and extracted in order to use the **split_net -batch** command.

The **insert_buffer -on_route -repeater_distance**, **legalize_placement**, and **split_net** commands are used together to split nets with routing into many nets using the same routing. The split_net_batch.tcl file is generated to hold the sequence of nets, so

that the entire set of nets can be split in a batch after legalization. By splitting the nets in a batch, the router is started only once and the log file is much shorter. The `split_net_batch.tcl` file (and another temporary file named `split_net_batch`) are automatically deleted.

If the nets that you are buffering have wires or vias typed "BUS", then before `split_net -batch` you need to allow the router to reroute those nets with this command:

```
set_parameter -name rerouteBus -value 1 -module droute
```

If the design is only partially routed and you want to work on only those nets mentioned by `split_net`, then you may need this command, to prevent routing fixes on other (unrouted) nets:

```
set_parameter -name splitNetConnBrokenNet -value 0 -module droute
```

Helpful hint: You might want to make a snapshot of the design before inserting buffers on nets because the process of legalization might move some buffers off the original route and cause excess routing during the execution of the `split_net -batch` command. If you do not like the result of splitting, you can rerun the script on the snapshot and then edit the `split_net_batch.tcl` file before calling `split_net -batch`. An entire `split_net` command can be deleted or an individual net (not the first) can be deleted from a list of nets. The routing for the deleted nets must then be completed by using the `route_eco` command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how two `insert_buffer` -`on_route` -`repeater_distance` commands generate a file called `split_net_batch.tcl` in the current directory. This file contains `split_net` commands specifying which nets should have their routing split at a later time.

The `legalize_placement` command is called to put the new buffers (or inverters) in legal locations.

The `split_net -batch` command reads the `split_net_batch.tcl` file and reuses the routing from the original nets and adds the routing necessary to reach the legalized buffers.

```
prompt> insert_buffer [get_net long_net] slow/BUFX4 -on_route -repeater_distance 50  
-new_net_names ibn -new_cell_names ibc  
prompt> insert_buffer [get_net longer_net] slow/BUFX4 -on_route -  
repeater_distance 80  
-new_net_names ibn -new_cell_names ibc  
prompt> legalize_placement -cells [get_cells -hier ibc*]
```

```
prompt> split_net -batch
```

In the following example, the split_net_batch.tcl file has the following format:

```
prompt> split_net {long_net ibn ibn_1 ibn_2} -cells {ibc ibc_1 ibc_2}
prompt> split_net {longer_net ibn_3 ibn_4 ibn_5 ibn_6}
-cells {ibc_3 ibc_4 ibc_5 ibc_6}
```

You can delete commands or nets from this file before applying the **split_net -batch** command, to avoid generating undesirable results.

If you do not want to use the commands in split_net_batch.tcl, you can use the **split_net -start** command to start over with a new sequence of **insert_buffer** commands, as shown below:

```
prompt> split_net -start
prompt> insert_buffer [get_net fanout_net] slow/BUFX4 -on_route -divide_load_by 2
prompt> insert_buffer [get_net signal_net] slow/BUFX4 -on_route -divide_load_by 3
prompt> legalize_placement -cells [get_cells -hier eco*]
prompt> set_parameter -name rerouteBus -value 1 -module droute
prompt> split_net -batch
```

SEE ALSO

[insert_buffer\(2\)](#)

split_objects

Splits one or more objects at the specified x or y coordinate or by a specified line.

SYNTAX

```
new_objects split_objects
{-x float | -y float | -line line}
[-gap float]
objects
```

Data Types

objects collection

ARGUMENTS

-x float

Specifies the x-coordinate at which to split the objects.

This is essentially the same as splitting by a vertical line from (x,-infinity) to (x,+infinity).

-y float

Specifies the y-coordinate at which to split the objects.

This is essentially the same as splitting by a horizontal line from (-infinity, y) to (+infinity, y).

-line line}

Specifies the line to use to split the objects.

If the specified line is not horizontal or vertical, the longest direction of the line is used to specify the direction and the average of the points is used for the position. For example, a line from (10,10) to (20,30) becomes a vertical line at the x value 15 ((10 + 20)/2).

Note: Only objects whose bounding box intersect the line are split.

-gap float

Specifies the gap to leave between the cut objects.

The gap is centered at the cut point and is either horizontal or vertical depending on the cut direction.

objects

Specifies the objects to be split, which can be net shapes, wiring keepouts, placement keepouts or voltage areas.

RETURNS

new_objects

Contains a list of the new split objects.

Note: The command is guaranteed to return the new list of objects after the split. Objects that are not split are returned unchanged and objects that are split have the new split objects returned. For example, if you split two wires

(W1 and W2) by a line that causes W2 to be replaced by two new wires (W2_1 and W2_2), the command returns three wires (W1, W2_1 and W2_2).

DESCRIPTION

This command splits one or more objects at the specified x or y coordinate or the specified line.

See the man page for the get_edit_property command for details of which objects can be split in x and y directions.

Note: Snapping is done automatically using the global snap settings.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example splits the currently selected objects at an x-coordinate of 100 and selects the new objects.

```
prompt> change_selection [split_objects -x 100 [get_selection]]
```

The following example splits the currently selected objects using a vertical line.

```
prompt> change_selection [split_objects -line {100 0 100 100} \  
[get_selection]]
```

SEE ALSO

get_object_snap_type(2)
```

spread_spare_cells

Places the specified cells evenly throughout a rectilinear region.

SYNTAX

```
status spread_spare_cells
cells
[-bbox spare_cells_region
 | -poly {{x1 y1} {x2 y2} ...}]
```

Data Types

<i>cells</i>	collection
<i>spare_cells_region</i>	rectangle
<i>x1</i>	float
<i>y1</i>	float
<i>x2</i>	float
<i>y2</i>	float

ARGUMENTS

<i>cells</i>	Specifies a collection of spare cells to spread.
<i>-bbox <i>spare_cells_region</i></i>	Specifies the rectangular region in which to spread spare cells.
<i>-poly {{<i>x1</i> <i>y1</i>} {<i>x2</i> <i>y2</i>} ...}</i>	Specifies the rectilinear region in which to spread spare cells, given as a list of x,y coordinates for the lower-left and upper-right corners.

DESCRIPTION

This command spreads a collection of spare cell instances over a given rectilinear region. The cells in the collection must be marked as spare cell by using the **set_attribute** command or created by using the **insert_spare_cells** command. The command ignores a cell that is not properly marked.

The placement of cells is not guaranteed to be legal. You should run the **legalize_placement** command to get a legal placement, if necessary.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example put cells of pattern *spare* inside a rectangular region.

```
prompt> spread_spare_cells\n-bbox {{10.8 20.3} {40.4 50.1}} [get_cells spare*]
```

The following example put cells *spareA* and *spareB* inside a polygonal region.

```
prompt> spread_spare_cells\n-poly {{10.8 20.3} {40.4 20.3} {40.4 50.1} \n{25.0 50.1} {25.0 30.3} {10.8 30.3} {10.8 20.3}} \n"spareA spareB"
```

SEE ALSO

`insert_spare_cells(2)`
`set_attribute(2)`

spread_zrt_wires

Spreads the wires in the opened cell for DFM.

SYNTAX

```
spread_zrt_wires
[-min_jog_length min_ratio]
[-pitch number_of_pitches]
[-timing_preserve_nets {collection_of_nets}]
[-timing_preserve_setup_slack_threshold slack_value]
[-timing_preserve_hold_slack_threshold slack_value]
```

Data Types

<i>min_ratio</i>	integer
<i>number_of_pitches</i>	float
<i>collection_of_nets</i>	collection or list
<i>slack_value</i>	float

ARGUMENTS

-min_jog_length *min_ratio*

Sets the minimal value of the ratio of jog length to layer pitch. By default, the *min_ratio* value is **2**.

-pitch *number_of_pitches*

Sets the spread value in terms of number of pitches. By default, the *num_of_pitches* value is **0.5**.

-timing_preserve_nets {*collection_of_nets*}

Specifies the nets to preserve timing on. If you specify this option, the command will consider the specified nets as timing critical and will skip spreading on these and the neighboring nets.

-timing_preserve_setup_slack_threshold *slack_value*

Specifies the slack threshold for timing critical nets. If you specify this option, the command will skip spreading on all nets with worst setup slack less than or equal to this value and the neighboring nets.

-timing_preserve_hold_slack_threshold *slack_value*

Specifies the slack threshold for timing critical nets. If you specify this option, the command will skip spreading on all nets with worst hold slack less than or equal to this value and the neighboring nets.

DESCRIPTION

This command spreads the wires in the opened cell for DFM. When spreading, a piece of original wire is broken and pushed away and jog wires are created at both ends to maintain a connection.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following example performs wire spreading using the *min_jog_length*, and *pitch* options.

```
prompt> spread_zrt_wires -pitch 0.5
```

SEE ALSO

widen_zrt_wires(2)

stretch_wire

Stretches given wires or contacts horizontally or vertically without loosing connections.

SYNTAX

```
status stretch_wire
objects
{-x distance | -y distance}
[-snap_to_track yes | no | halftrack]
[-jog_layer same | up | down]
[-auto_repair_net]
[-end_point_range distance]
[-undo]
```

ARGUMENTS

```
objects
Collection of wires or contacts.

-x distance

-y distance
Select the delta x or y by which to move given wires or contacts. All
distances are in unit of micron.

-snap_to_track yes | no | halftrack
Select snap to track: yes | no | halftrack. If this option is skipped, yes
is default.

-jog_layer same | up | down
Selects the jog layer for jogs in the wire.
same means same layer as the given wires.
up means layer one level higher than the layer of the given wires.
down means layer one level below the layer of the given wires.
If this option is skipped, same is default.

-auto_repair_net
Select trim redundant net objects or antenna and reconnect them in a symbolic
connection model.

-end_point_range distance
Specifies an endpoint extension range. If a wire extends past a contact but
is less than this range, the connection is treated as an endpoint connection.
If the contact is stretched shorter, the wire stretches with the contact. If
the extension past the contact is greater than the endpoint value, the
connection is treated as a T-connection and the wire is not trimmed. Default
is 0.0

-undo
Restores the wires to the state that was before the last stretch_wire run.
```

DESCRIPTION

Stretches given wires horizontally or vertically without loosing connections. You can change more than one wire at a time by providing collection of several wires. Signal wires are stretched according to the center-line.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

To move selected wires in x direction with auto repair and end point ranges options
.nf stretch_wire -x 10.0 -jog_layer same -snap_to_track halftrack -auto_repair_net -end_point_range 0.1 [get_selection]

SEE ALSO

get_selection(2)
get_net_shapes(2)
get_vias(2)

sub_designs_of

Gets the subdesigns according to the options.

SYNTAX

```
collection sub_designs_of
[-hierarchy]
[-in_partition | -partition_only]
[-dt_only | -ndt_only]
[-multiple_instances | -single_instances]
[-names_only]
design
```

ARGUMENTS

-hierarchy

Returns all subdesigns in the hierarchy of the specified design. By default, only the children of the specified design are returned.

-in_partition

Returns only subdesigns that are part of the partition containing the specified design.

This option and the **-partition_only** option are mutually exclusive.

-partition_only

Looks only at subdesigns that are compile partitions (subdesigns that have the **in_partition** attribute set). Specifically, it returns the direct child compile partitions of the specified design (even if they are more than one level away). With the **-hierarchy** option, it returns all compile partitions in the hierarchy below the specified design.

This option and the **-in_partition** option are mutually exclusive.

-dt_only

Returns only subdesigns that are at least instantiated once with the **dont_touch** attribute set.

This option and the **-ndt_only** option are mutually exclusive.

-ndt_only

Returns only subdesigns that are at least instantiated once with the **dont_touch** attribute not set.

This option and the **-dt_only** option are mutually exclusive.

-multiple_instances

Returns only subdesigns that are instantiated multiple times.

This option and the **-single_instances** option are mutually exclusive.

-single_instances

Returns only subdesigns that are instantiated once.

This option and the **-multiple_instances** option are mutually exclusive.

-names_only

Returns a list of design names, instead of a collection.

`design`

Specifies the design whose subdesigns will be returned.

DESCRIPTION

The **sub_designs_of** command returns a collection of subdesigns of the specified design (or a Tcl list of design names if the **-names_only** option is specified). By default, the command returns the hierarchical children of the specified design. You can return all subdesigns in the hierarchy by specifying the **-hierarchy** option. In addition, you can filter the results in the following ways:

- subdesigns that are the top-level of a partition (`-partition_only`)
- subdesigns within the partition that contains the specified design (`-in_partition`)
- subdesigns that are at least instantiated once with the **dont_touch** attribute set (`-dt_only`)
- subdesigns that are instantiated at least once with the **dont_touch** attribute not set (`-ndt_only`)
- subdesigns that have multiple instances (`-multiple_instances`)
- subdesigns that have a single instance (`-single_instances`)

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

`get_attribute(2)`
`set_attribute(2)`
`set_dont_touch(2)`
`sub_instances_of(2)`

sub_instances_of

Gets the subinstances according to the options.

SYNTAX

```
collection sub_instances_of
[-hierarchy]
[-in_partition] [-partition_only]
[-dt_only] [-ndt_only]
[-of_references reference_list]
[-master_instance]
[-names_only]
design
```

ARGUMENTS

-hierarchy

Returns all subinstances in the hierarchy of the specified design.
By default, only the children of the specified design are returned.

-in_partition

Returns only subinstances that are part of the partition that contains the specified design.
This option and the **-partition_only** option are mutually exclusive.

-partition_only

Looks only at subinstances that are the top-level designs of compile partitions (subdesigns that have the **in_partition** attribute set). Specifically, it returns the instances that reference the next direct child compile partitions below the specified design (even if the instances are more than one level of hierarchy away). With the **-hierarchy** option, it returns all compile partition instances in the hierarchy below the specified design.
This option and the **-in_partition** option are mutually exclusive.

-dt_only

Returns only subinstances that have the **dont_touch** attribute set.
This option and the **-ndt_only** option are mutually exclusive.

-ndt_only

Returns only subinstances that do not have the **dont_touch** attribute set.
This option and the **-dt_only** option are mutually exclusive.

-of_references *reference_list*

Specifies the reference designs whose instances will be returned.
By default, the **sub_instances_of** command returns instances for all reference designs.

-master_instance

Returns only the master instance when a design has multiple instances.
By default, the **sub_instances_of** command returns all instances of a multiply instantiated design.

```
-names_only
    Returns a list of instance names, instead of a collection.

design
    Specifies the design whose subinstances will be returned.
```

DESCRIPTION

This command returns a collection of instances of the specified design (or a Tcl list of instance names, if the **-names_only** option is specified). By default, it returns only the direct children of the design, if the **-hierarchy** option is specified, all instances of the entire design subtree are returned. If the **-master_only** option is specified, it will return only one instance for multiply instantiated designs. It will pick the master instance (i.e. the one that has the **MasterInstance** attribute set). If none of the qualifying instances (according to the other options) is the master instance, any instance of that design will be returned.

In addition, you can filter the results in the following ways:

- subinstances that are the top-level of a partition (**-partition_only**)
- subinstances within the partition that contains the specified design (**-in_partition**)
- subinstances that have the **dont_touch** attribute set (**-dt_only**)
- subinstances that do not have the **dont_touch** attribute set (**-ndt_only**)
- instances of certain designs (**-of_references**)

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

`get_attribute(2)`
`set_attribute(2)`
`set_dont_touch(2)`
`sub_designs_of(2)`

suppress_message

Disables printing of one or more informational or warning messages.

SYNTAX

```
string suppress_message
[message_list]
```

Data Types

message_list list

ARGUMENTS

message_list
A list of messages to suppress.

DESCRIPTION

The **suppress_message** command provides a mechanism to disable the printing of messages. You can suppress only informational and warning messages. The result of **suppress_message** is always the empty string.

A given message can be suppressed more than once. So, a message must be unsuppressed (using **unsuppress_message**) as many times as it was suppressed in order for it to be enabled. The **print_suppressed_messages** command displays the currently suppressed messages.

EXAMPLES

When the argument to the **unalias** command does not match any existing aliases, the CMD-029 warning message displays. This example shows how to suppress the CMD-029 message:

```
prompt> unalias q*
Warning: no aliases matched 'q*' (CMD-029)
prompt> suppress_message CMD-029
prompt> unalias q*
prompt>
```

SEE ALSO

print_suppressed_messages(2)
unsuppress_message(2)

swap_cell_locations

Swaps the locations of two cells.

SYNTAX

```
int swap_cell_locations
cell1
[-cell1_orient N | W | S | E | FN | FE | FS | FW]
[-cell2_orient N | W | S | E | FN | FE | FS | FW]
```

Data Types

cell1 collection

ARGUMENTS

cell1

Specify the first cell to be swapped. The collection should only have one cell.

-cell1_orient N | W | S | E | FN | FE | FS | FW

Specifies the orientation of first cell after swapping. By default, the other cells' orientation will be assumed.

-cell2_orient N | W | S | E | FN | FE | FS | FW

Specifies the orientation of second cell after swapping. By default, the other cells' orientation will be assumed.

DESCRIPTION

This command swaps the locations of two cells. Following Milkyway convention, the location of a cell refers to its lower left corner regardless of its orientation. The lower left coordinates of the two cells are swapped.

By default, the orientation of the cell after swap assumes the orientation of the other cell.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example swaps the locations of the two cells A and B:

```
prompt> swap_cell_locations A B
1
```

SEE ALSO

`move_objects(2)`

syntax_check

Enables or disables the Syntax Checker's syntax_check mode which checks commands for syntax errors.

SYNTAX

```
integer syntax_check
true | false
```

ARGUMENTS

true | false

Indicates whether to enable or disable the syntax_check mode. A value of **true** enables the mode and **false** disables the mode. Set the related command **context_check** to **false** before setting **syntax_check** to **true**.

DESCRIPTION

This command, with **context_check**, comprises a pair of commands that enable or disable the syntax_check or context_check modes of the dc_shell Syntax Checker. In the syntax_check mode, the command interpreter checks each command for the correct syntax. To find out whether either mode is enabled, retrieve the the value of the corresponding status variable (**context_check_status** or **syntax_check_status**), by running either the **printvar syntax_check_status** or the **printvar context_check_status** command.

Using syntax_check mode, you can identify and correct syntax errors in a script file that you want to include, before you actually execute the file. The command interpreter checks for the existence of the included file and parses the file line by line, to check its syntax. As errors (spelling, typos, invalid or missing arguments) are found, the normal error messages are issued but syntax checking continues to the end of the file.

Note that the syntax_check mode examines each line only once; it does not iterate through loops. Thus, there is a possibility of receiving false error messages if names are not found that would be generated during normal execution. For example, the syntax_check mode might make variable assignments as they occur line by line in the script. In that case, the value of the variable might be the one that appears in the variable assignment that physically appears last in the code. This value might be different from the value that the variable would have if the code were executed.

For details about the features of the syntax_check and the context_check modes, see the *Design Compiler Command-Line Interface Guide*.

EXAMPLES

The following example enables the syntax_check mode, checks the file named myfile.tcl for syntax errors, and redirects the output to myfile.out.

```
prompt> syntax_check true
```

```
Syntax checker on.  
prompt> source myfile.tcl > myfile.out
```

In the following example, you determine whether **context_check** is enabled before attempting to enable **syntax_check**. The status of the variable shows that **context_check** is currently enabled, probably by a previous operation. Disable **context_check** and then enable **syntax_check**.

```
prompt> printvar context_check_status  
true  
prompt> context_check false  
Context checker off.  
prompt> syntax_check true  
Syntax checker on.
```

SEE ALSO

[context_check_status\(3\)](#)
[syntax_check_status\(3\)](#)

synthesize_fp_rail

Synthesizes power networks or power switch arrays based on user-specified constraints. In a single run, you can synthesize either a power network for a single voltage design, power networks for a multivoltage design, or a power switch array.

SYNTAX for Single Voltage Power Network Synthesis

```
status synthesize_fp_rail

[-synthesize_power_plan]
[-synthesize_power_pads]

```

Data Types for Multivoltage Power Network Synthesis

voltage areas list

ARGUMENTS

-synthesize_power_plan
Performs normal power network synthesis.
This is the default behavior if you do not specify any of the following options: **-synthesize_power_pads**, **-synthesize_voltage_areas**, and **-synthesize_power_switch_array**.
This option can be specified together with the **-synthesize_power_pads** option to perform simultaneous power network and power pad synthesis.
This option is mutually exclusive with the **-synthesize_voltage_areas** and **-synthesize_power_switch_array** options.

-synthesize_power_pads
Performs power pad synthesis.
This option can be specified together with the **-synthesize_power_plan** option to perform simultaneous power network and power pad synthesis.
This option is mutually exclusive with the **-synthesize_voltage_areas** and **-synthesize_power_switch_array** options.
If you do not specify any of the following options, the tool performs normal power network synthesis: **-synthesize_power_plan**, **-synthesize_power_pads**, **-synthesize_voltage_areas**, and **-synthesize_power_switch_array**.

-nets nets
Specifies the nets on which to perform power network synthesis or power pad synthesis. This is a required option for power network synthesis (**-synthesize_power_plan**) and power pad synthesis (**-synthesize_power_pads**). This option is not supported for multivoltage power network synthesis (**-synthesize_voltage_areas**) or power switch synthesis (**-synthesize_power_switch_array**).

-power_budget power
Specifies a total power budget for the design. The unit is milliwatts.

This power budget is allocated to each instance in the design based on the area of the instance area, unless the power in that instance is already defined. For a hierarchical block, the power budget is computed based on the sum of all cells and blocks inside it.

The power for an instance can be defined in the following ways: by performing power analysis (**-analyze_power**), by reading a default power file (**-read_default_power_file**), by reading a Power Compiler file (**-read_power_compiler_file**), or by reading a PrimePower file (**-read_prime_power_file**).

If the power is defined for one or more instances, the tool computes the sum of the defined instance power. If the sum of the defined instance power is greater than the total power budget, the tool ignores the total power budget. Otherwise, the tool allocates the remaining power budget among the instances without defined power.

For multivoltage power synthesis, this option is ignored if a power budget has already been specified for all voltage areas by the **set_fp_rail_voltage_area_constraints** command.

By default, the total power budget is 1000 mW unless you specify **-analyze_power**, in which case the default is 0.

-analyze_power

Perform power analysis on each instance by using the IC Compiler power analysis engine (the same engine that is used by the **report_power** command). Before using this option for power analysis, you can specify the toggle rate and static probability in the following ways:

- * Specify the default toggle rate by setting the **power_default_toggle_rate** variable. The default value is 0.1.
- * Specify the default static probability for primary inputs and black box outputs by setting the **power_default_static_probability** variable. The default value is 0.5.
- * Set the toggle rate and static probability for a specific object, such as a net, pin, or port, by using the **set_switching_activity** command.
- * Read the switching activity from a switching activity interchange format (SAIF) file by using the **read_saif** command.
- * Set the power value of a pin per toggle by using the **set_cell_internal_power** command.

Before performing power network synthesis (PNS) with **-analyze_power**, you should run the **report_power -cell -flat -nosplit** command. For more information, see the **report_power** man page.

You can use this option together with the **-read_default_power_file** option. The power specified in the default power file has a higher priority than that calculated by the **-analyze_power** option. If the power value for a given instance is both calculated and read from the default power file, the instance is assigned the power value from the default power file.

This option is mutually exclusive with the **-read_power_compiler_file** and **-read_prime_power_file** options.

-read_default_power_file power_file_name

Specifies the default power report file to use to assign power to each instance. The format of this file is as follows:

```
instance|master name power_value  
The unit for the power value is mW.
```

For example, to specify a power value of 0.2 mW for instance X1 and a power value of 0.1 mW for reference cell abc.FRAM, the file would contain the following lines:

```
instance X1 0.2  
master abc.FRAM 0.1
```

You can generate a default power file by running the **synthesize_fp_rail** or **analyze_fp_rail** command. These commands generate a file called You can use this option with the **-power_budget** and **-analyze_power** options. This option is mutually exclusive with the **-read_default_power_file** and **-read_prime_power_file** options.

-read_power_compiler_file power_compiler_report_file

Specifies the Power Compiler report file to use to assign power to each instance.

You can use this option with the **-power_budget** option.
This option is mutually exclusive with the **-analyze_power**, **-read_default_power_file** and **-read_prime_power_file** options.

-read_prime_power_file prime_power_report_file

Specifies the PrimePower or PrimeTime PX report file to use to assign power to each instance.

You can use this option with the **-power_budget** option.
This option is mutually exclusive with the **-analyze_power**, **-read_default_power_file** and **-read_power_compiler_file** options.

-target_voltage_drop target_voltage

Specifies a target voltage (IR) drop value for single-voltage power network synthesis to succeed. The unit is millivolts.

By default, 10 percent of the supply voltage value is used as the target voltage drop.

This option is ignored for multivoltage power network synthesis and power switch synthesis. You must specify the target voltage drop for each voltage area by using the **set_fp_rail_voltage_area_constraints** command.

-lowest_voltage_drop

Allows single-voltage power network synthesis to generate the power network that has the lowest possible voltage (IR) drop based on user-specified power network constraints.

This option is ignored for multivoltage power network synthesis and power switch synthesis. To specify this option for a voltage area, you must use the **set_fp_rail_voltage_area_constraints** command.

-pad_masters pad_reference_cells

Specifies the pad reference cells and their associated nets as follows:

[net_name:]pad_reference_cell

If the net name is not specified, the pad reference cell is used for both power and ground nets.

By default, PNS assumes that all pads logically connected to signal 1 or 0 are power pads.

You can use this option together with **-read_pad_instance_file** or **-read_pad_master_file**.

-read_pad_instance_file *pad_instance_file_name*
Specifies the power and ground (PG) pad instances by using an input file. The instances specified in the file are used as PG pads. The format is:

instance_name [*net_name*]
For example, to specify that the VDD1 pad instance is used for the VDD net, enter

VDD1 VDD
If you do not specify a net name, the command assumes that the specified pad instance is used for both power and ground nets.
This option and **-read_pad_master_file** are mutually exclusive; you can specify only one. You can use this option together with **-pad_masters**.

-read_pad_master_file *pad_reference_cell_file_name*
Specifies the PG pad reference cells by using an input file. The reference cells specified in the file are used as PG pad reference cells. The format is:

reference_cell_name *net_name*
For example, to specify that the VDD.FRAM reference cell is used for the VDD net, enter

VDD.FRAM VDD
If you do not specify a net name, the command assumes that the specified pad reference cell is used for both power and ground nets.
This option and **-read_pad_instance_file** are mutually exclusive; you can specify only one. You can use this option together with **-pad_masters**.

-use_pins_as_pads
Allows power network synthesis to use PG pins on the design boundary as PG pads. This option is useful in block-level power network synthesis.

-use_strap_ends_as_pads
Allows power network synthesis to use the ends of straps at the design boundary or core ring as power pads. This option is useful at the design planning stage when PG pads have not yet been created.

-top_level_only
Ignores cell instances inside soft macros during power network synthesis. By default, power network synthesis flattens all cell instances in each soft macro.

-create_virtual_rails *layer*
Creates pseudo-straps on the specified metal layer to connect standard cell pins in the row grid. These virtual straps are used only for IR drop analysis in power network synthesis. They will not be created after commit.
By default, metall1 is used to generate the pseudo-straps.

-ignore_blockages
Ignores any blockage for virtual pads to make a pseudo-connection to the power network.
By default, the tool honors blockages for virtual pads.

-honor_conn_view_layers *conn_layer*
Specifies the metal layers in which the connectivity (CONN) views are

honored. To honor the CONN view in all metal layers, use the keyword **all** as the layer name.

By default, CONN views are not honored in any metal layer.

-output_directory directory_name

Specifies the directory in which to store the voltage drop and electromigration results.

The default is ./pna_output.

-synthesize_voltage_areas

Performs multivoltage power network synthesis on voltage areas that have been specified by using the **set_fp_rail_voltage_area_constraints** command.

This option is mutually exclusive with the **-synthesize_power_plan**, **-synthesize_power_pads**, and **-synthesize_power_switch_array** options.

If you do not specify any of the following options, the tool performs normal power network synthesis: **-synthesize_power_plan**, **-synthesize_power_pads**, **-synthesize_voltage_areas**, and **-synthesize_power_switch_array**.

-synthesize_power_switch_array

Performs power switch synthesis on the specified powered-down voltage area.

This option is mutually exclusive with the **-synthesize_power_plan**, **-synthesize_power_pads**, and **-synthesize_voltage_areas** options.

If you do not specify any of the following options, the tool performs normal power network synthesis: **-synthesize_power_plan**, **-synthesize_power_pads**, **-synthesize_voltage_areas**, and **-synthesize_power_switch_array**.

-voltage_areas voltage_areas

Specifies the voltage areas in which to perform multivoltage power network synthesis or power switch synthesis.

For multivoltage power network synthesis, you can specify multiple voltage areas. If you do not specify this option, power networks are synthesized in all voltage areas that have been specified by the

set_fp_rail_voltage_area_constraints command.

For power switch synthesis, this is a required option and you can specify only a single voltage area.

-voltage_supply float

Specifies the supply voltage for the synthesized power nets in a single voltage design. The unit is volts.

By default, the supply voltage is 1.5 V.

This option is ignored for multivoltage power network synthesis and power switch synthesis. You must specify the supply voltage for each voltage area by using the **set_fp_rail_voltage_area_constraints** command.

DESCRIPTION

This command allows you to synthesize a power network with a specified IR (voltage) drop and electromigration (EM) constraints, power budgets, and customized design style (for example, with or without a core ring, specific metal layers, stacked via, and so on). It can perform single-voltage power network synthesis, single-voltage power pad synthesis, multivoltage power network synthesis, or power switch synthesis.

Power network synthesis (PNS) enables you to preview an early power network at the

design planning stage.

After PNS, if the IR drop and electromigration meet the requirements, you can commit the synthesized power network into a real power network by using the **commit_fp_rail** command. To commit the synthesized power switches, you must run the `create_power_switch.tcl` script that is written to the `pna_output` directory when you perform power switch synthesis.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example shows how to synthesize a power network for the VDD and VSS nets with a power budget of 1000 mW and a supply voltage of 1.2 V. The pad reference cells are `pvdi.FRAM` for the VDD net and `pvdo.FRAM` for the VSS net.

```
prompt> synthesize_fp_rail -nets {VDD VSS} \
-power_budget 1000 -voltage_supply 1.2 \
-pad_masters "VDD:pvdi.FRAM VSS:pvdo.FRAM"
```

The following example shows how to synthesize a power network for the VDD and VSS nets. The power is analyzed by IC Compiler and the supply voltage 1.2 V.

```
prompt> synthesize_fp_rail -nets {VDD VSS} \
-analyze_power -voltage_supply 1.2
```

The following example shows how to synthesize a power network in multiple voltage areas with different power supplies.

```
prompt> synthesize_fp_rail \
-synthesize_voltage_area -voltage_area {MULTIPLIER DEFAULT_VA}
```

The following example shows how to synthesize power switches in the powered-down voltage area named `PWR_DN`.

```
prompt> synthesize_fp_rail \
-synthesize_power_switch_array -voltage_area PWR_DN
```

```

trace_scan_chain

Traces scan chain in the current design.

SYNTAX

```
status trace_scan_chain
[-from scan_input] [-to scan_output]
```

Data Types

<i>scan_input</i>	string
<i>scan_output</i>	string

ARGUMENTS

```
-from scan_input
      Specify the start point of the scan chain.

-to scan_output
      Specify the stop point of the scan chain.
```

DESCRIPTION

Traces the scan chain in the current design backwards from the user-specified scan-out pin to the scan-in pin. A correctly traced scan chain is updated in the Milkyway. Tracing through scan cells and single-input cells is automatic. Any other leaf cell requires the user to specify the scan-in and scan-out pins by using *set_scan_pin_type*. Arguments for the -from and -to options are instance pins or ports. After *trace_scan_chain*, *check_scan_chain* is recommended to do the verification.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows a new chain is generated.

```
prompt> trace_scan_chain -from TESTSII1 -to u0/u0/U2/A

===== Scan Trace =====
INFO: reading in existing scan chain group...
Total number of edges in scan chain group is 1730
Number of scan pins processed is 1725

translate_zrt_parameters

Translates the routing parameters to Zroute.

SYNTAX

```
status translate_zrt_parameters
[-output filename]
```

Data Types

filename string

ARGUMENTS

```
-output filename
    Writes the Tcl translation script to the specified file name.
    By default, a Tcl script is not generated.
```

DESCRIPTION

The **translate_zrt_parameters** command does translation between Zroute options and routing parameters. A parameter will only be translated if it has been set by the user explicitly before the translation command. A parameter will also be translated if its value is different than the default value (e.g. the value has been saved with the cell), but only if the corresponding option to be translated to has not been set by the user explicitly.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example translates routing parameters to Zroute options.

```
prompt> translate_zrt_parameters -output translate_script.tcl
```

SEE ALSO

trim_fill_eco

Trims the metal fill. Use this command after you finish inserting metal fill and running ECO routing.

SYNTAX

```
status trim_fill_eco
[-input fill_view_name]
[-output fill_view_name]
[-spacing_to_routing number]
[-remove_vio_fill]
[-from_metal metal_layer_name]
[-to_metal metal_layer_name]
```

Data Types

<i>fill_view_name</i>	string
<i>number</i>	float
<i>metal_layer_name</i>	string

ARGUMENTS

```
-input fill_view_name
    specify the fill view in which the fill will be trimmed, without specifying
    this option means the tool will read fills from the editing cell itself

-output fill_view_name
    specify the fill view in which the trimmed fills will be saved, without
    specifying this option means the tool will save the fills to the editing cell
    itself

-spacing_to_routing number
    the floatValue will multiplied by the minimum spacing, and the result will
    be used to control the spacing between fill to routing, the fill within this
    spacing will be trimmed off. Default : 1.0

-remove_vio_fill
    remove whole fill segment with DRC violation

-from_metal metal_layer_name
    specify the name of the bottom layer to start the trimming of fill. The
    metal_layer_name must match a layer name in the database. If no
    bottom_layer_name is specified, metall is the default bottom layer.

-to_metal metal_layer_name
    specify the name of the top layer to end the trimming of fill. The
    metal_layer_name must match a layer name in the database. The corresponding
    layer should be the same as or above the bottom layer. If no top_layer_name
    is specified, the topmost metal layer of the design is the default top metal
    layer.
```

DESCRIPTION

When you have finished metal filling and the engineering change order has changed the routing, you can use this command to trim the metal fill and avoid design rule constraint violations.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example will read the fills from the editing cell and trim the fill and output to cell "aaa.fill" :

```
prompt> trim_fill_eco -output aaa.fill
```

The following example will read the fills from an existing fill view "bbb.fill" and trim the fill metal from layer METAL2 to METAL4 and output to cell "ccc.fill" :

```
prompt> trim_fill_eco -input bbb.fill -output aaa.fill -from_metal METAL2 -  
to_metal METAL4
```

SEE ALSO

`insert_metal_filler(2)`

unalias

Removes one or more aliases.

SYNTAX

```
string unalias
pattern
```

ARGUMENTS

DESCRIPTION

The **unalias** command removes aliases created using the alias command.

EXAMPLES

The following command removes all aliases.

```
prompt> unalias *
```

The following command removes all aliases beginning with f, and the alias rt100.

```
prompt> unalias f* rt100
```

SEE ALSO

`alias(2)`

uncommit_fp_soft_macros

Transforms soft macros into plan groups.

SYNTAX

```
status uncommit_fp_soft_macros
[-push_up_preroutes pg | none]
[-remove_feedthroughs]
[objects]
```

ARGUMENTS

-push_up_preroutes pg | none

Specifies command will push up just pg routing or no routing at all. If this option is not specified, the default behavior of uncommit_fp_soft_macros is to push up ALL routing, including both PG and detail routing. This option allows the user to choose JUST PG, or no routing at all. The user should be cautioned that the use of the "none" value along with this option will result in the loss of any existing child routing during the uncommit process, and the use of the "pg" option will result in the loss of any detail routing in the child cell. This option used with a route_type of pg will push up all P/G routing, regardless of whether it was originally a part of the plan group or whether it was a global type P/G net.

-remove_feedthroughs

Removes feedthrough ports on soft macros

objects

Collection of soft macros. If no collection is specified, then all soft macros are processed.

DESCRIPTION

This command transforms soft macros into plan groups. For each soft macro processed: the soft macro is disconnected and deleted, a plan group with the soft macro's boundary is created, and all of the plan group's standard cells are created and connected to their corresponding nets.

The command by default creates child level power meshes and detailed routing at its relative place in the flat design. The command can also has the capability to limit routing that is pushed up to just PG routing, or no routing at all. Unlike commit_fp_plan_groups (which automatically pushes down internal net routes but requires the -push_down_power_and_ground_straps option in order to include global P/G nets), uncommit_fp_soft_macros makes no distinction about what to push up (it pushes up both internal net routes and global net routes automatically), unless the -push_up_preroutes option is used to specify either just P/G type routes (including internal P/G net routes), or no routes. The user may wish to run push_up_fp_objects using route types prior to running uncommit_fp_soft_macros to push up just the global-type power and ground nets that may have been pushed down previously by either employing the -push_down_power_and_ground_straps during commit, or by running push_down_fp_objects after commit. The distinction is that if a port was added to

the soft macro as a result of a push-down routing operation (either `push_down_fp_objects` with `routing` of `commit` with the `-push_down_power_and_ground_straps` option), an explicit push-up using `push_up_fp_objects` will remove that port and then `uncommit` will produce a plan group without that port on the plan group. If it is left to `uncommit` to push up the global power or ground net routing, such an added port will remain on the plan group's hierarchical cell instance and an internal hierarchical power or ground net will be retained by the plan group. If that is not desired, then run `push_up_fp_objects` prior to `uncommit` so that global-type routes can be distinguished from internal type net routes. The command also allows the user to remove feedthrough ports on a given soft macro.

The command takes a collection of soft macros as an argument. The command will process the soft macros in the collection. If no collection is given, then all soft macros are processed.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

Uncommit entire design and push up all routing

```
uncommit_fp_soft_macros
```

Uncommit entire design and push up just PG routing

```
uncommit_fp_soft_macros -push_up_preroutes pg
```

Uncommit selected soft macros, remove feed throughs, and push up no routing

```
uncommit_fp_soft_macros -push_up_preroutes none -remove_feedthroughs $SM_List
```

SEE ALSO

```
commit_fp_plan_groups(2)  
push_up_fp_objects(2)
```

undo

Undoes the last operation.

SYNTAX

```
status undo
[-all]
[-mark string]
```

ARGUMENTS

-all	Undo all operations in undo stack.
-mark <i>string</i>	Undo all operations in undo stack to the named mark.

DESCRIPTION

This command undoes one or more undoable operations.

The undone commands can be redone using the **redo** command.

EXAMPLES

The following example undoes the result of the **move_objects** command.

```
prompt> move_objects -to {1400 1600} [get_route_guides *]
prompt> undo
```

SEE ALSO

```
redo(2)
undo_mark(2)
undo_config(2)
```

undo_config

Configures the undo stack.

SYNTAX

```
status undo_config
{-max_depth int | -max_memory int
 | -depth int
 | -memory int
 | -enable
 | -disable}
-enabled sbool
```

ARGUMENTS

-max_depth int

Set the maximum depth for the undo stack

Note: If the value is set to zero then maximum depth checking is disabled.

-max_memory int

Set the maximum memory usage for the undo stack

Note: If the value is set to zero then maximum memory checking is disabled.

-depth int

Set the current depth of the undo stack

-memory int

Set the current memory usage for the undo stack

-enable

Re-enables the undo stack after it is disabled. See **-disable** option for more details.

-disable

Disables the undo stack. The undo is cleared and no new commands are added to the stack until it is enabled.

This option is useful if the user is about to make a large number of changes which he/she knows that they are not going to undo. Disabling in this case will not waste memory and also speed up the command processing.

DESCRIPTION

This command configures the undo stack.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example clears the undo stack by setting the depth to zero:

```
> undo_config -depth 0
```

The following example disables undo, runs a complex command and re-enables undo:

```
> undo_config -disable
> remove_objects [get_plan_groups *]
> undo_config -enable
```

SEE ALSO

[undo\(2\)](#)
[redo\(2\)](#)
[undo_mark\(2\)](#)

undo_mark

Marks a position in the undo stack to undo back to.

SYNTAX

```
status undo_mark
      mark
```

ARGUMENTS

mark
Name of the mark to undo back to

DESCRIPTION

This command marks a position in the undo stack that can be undone back to with a single undo command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example adds a mark, does two moves, and then undoes them as a single operation.

```
prompt> undo_mark -mark move_mark
prompt> move_objects -to {1400 1600} [get_cell alu1]
prompt> move_objects -to {1600 1600} [get_cell mem1]
prompt> undo move_mark
```

SEE ALSO

`undo(2)`
`redo(2)`
`undo_config(2)`

ungroup

Removes a level of hierarchy.

SYNTAX

```
status ungroup
cell_list | -all
[-prefix prefix_name]
[-flatten]
[-simple_names]
[-soft]
[-small n]
[-force]
[-start_level n]
[-all_instances]
```

Data Types

cell_list	list
prefix_name	string
n	integer

ARGUMENTS

cell_list

Specifies a list of cells in the current design that are to be ungrouped. The contents of these cells are brought up to the same level as the cells. You must specify either **cell_list** or **-all**, but not both.

-all

Indicates that all cells in the current design or current instance are to be ungrouped. You must specify either **-all** or **cell_list**, but not both.

-prefix prefix_name

Specifies the prefix to use in naming ungrouped cells. The default naming style is as follows:

cell_being_ungrouped/old_cell_name{number}

To provide a vestige of the former hierarchy, omit this option when using the **-flatten** option

-flatten

Indicates that the specified cell and all of its subcells are to be exploded recursively until all levels of hierarchy are removed.

-simple_names

Indicates that simple, non-hierarchical names are to be used for cells that are ungrouped. Unless this option is used, cells are given default hierarchical names. With this option, cells maintain their original names.

-soft

Indicates that the **group_name** attribute is to be removed on the specified

cells. With the **-soft** and **-flatten options**, the **group_name** attribute is removed recursively down the hierarchy of the selected cells. The **group_name** attribute specifies cell grouping constraints for layout placement tools.

-small n

Causes all subdesigns with less than the number of leaf cells specified by *n* to be ungrouped. This option implies the **-all** option.

-force

Causes all **dont_touch** hierarchical cells to be flattened. The **dont-touch** attribute is inherited by their leaf cells. This option can only be used when either **-all** or *cell_list* is specified.

-start_level n

Causes all hierarchical cells which are at the level specified by *n* to be flattened. This option implies **-flatten** option. The value of level can be 1, 2, 3, and so forth. Specifying a value of 1 for **-start_level** flattens the cells from the current design. Specifying a value of 2 causes the top-level blocks to be maintained and all cells in each of the top-level blocks be flattened. The current instance cannot be set when this option is used. This option cannot be used with **-small** option.

-all_instances

Enables the command to accept instance cells that are not unique in the object list.

DESCRIPTION

Removes a single level of hierarchy from the current design by exploding the contents of the specified cell or cell instance in the current design.

Any cells that are marked **dont_touch** are left undisturbed. Black boxes are also not collapsed. Power Compiler-inserted clock gates are not collapsed by default. To do that, set the *power_cg_flatten* variable to TRUE before running **ungroup**.

New cell names are created by concatenating *prefix_name* with original cell names. If the resulting name is not unique, the new unique name is similar to the following:

<prefix_name>cell<number>

If the design contains instances (leaf cells) and only part of design hierarchy needs to be ungrouped, use **current_instance** to set the instance before ungrouping the cells within that design instance. Alternatively, you can use the full hierarchical name of the cell instance. When **current_instance** is defined, it is to be unique and when *cell instance* is used, the parent must be unique. This restriction to prevent design inconsistency.

If you do not specify a prefix, the default is

cell_being_ungrouped/old_cell_name{number}

If there are dangling nets in the design, they are removed by **ungroup**.

If timing derate is defined for the cell being ungrouped, the derates are pushed down to the lower-level cells if they or their library cells do not have the corresponding derates. This may cause timing inconsistency in the timing report before and after the ungrouping.

Use the **-all_instances** option when any cell in the object list is an instance in the lower hierarchy and its parent cell is not unique. All similar instance cells under the same parent design are ungrouped. The current design does not have to be changed in order to ungroup the instance cells in the lower design hierarchy. If none of the cells in the object list is an instance in the lower hierarchy, or if its parent cell is unique, the **-all_instances** option is not required.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example ungroups a specified list of cells:

```
prompt> ungroup {u1 u2 u3}
```

The following example ungroups a specific cell and specifies the prefix to be used:

```
prompt> ungroup {u1} -prefix "U1:"
```

The following example completely removes the hierarchy of two cells:

```
prompt> ungroup {u1 u2} -flatten
```

The following example completely collapses the hierarchy of the current design:

```
prompt> ungroup -all -flatten
```

The following example ungroups all cells in the design except u1:

```
prompt> set_dont_touch {u1}
```

```
prompt> ungroup -all
```

The following example hierarchically removes cell grouping constraints destined to drive layout placement tools, without modifying the design hierarchy:

```
prompt> ungroup -soft -flatten
```

The following example ungroups all cells under the instance A/B/C:

```
prompt> current_instance A/B
```

```
prompt> ungroup C
```

The following example flattens all cells starting at level 2:

```
prompt> ungroup -start_level 2
```

The following example ungroups the cell instance MID1/BOT1/FOO1 and MID1/BOT1/FOO2. MID1/BOT1 is a unique instantiation of design BOT.

```
prompt> ungroup {MID1/BOT1/FOO1 MID1/BOT1/FOO2}
```

SEE ALSO

`set_dont_touch(2)`
`power_cg_flatten(3)`
`ungroup_keep_original_design(3)`

uniquify

Removes multiply-instantiated hierarchy in the current design by creating a unique design for each cell instance.

SYNTAX

```
int uniquify
[-force]
[-base_name base_name]
[-cell cell_list]
[-reference design_name]
[-new_name new_design_name]
[-dont_skip_empty_designs]
```

Data Types

<i>base_name</i>	string
<i>cell_list</i>	list
<i>design_name</i>	string
<i>new_design_name</i>	string

ARGUMENTS

-force

Indicates that instances are to be renamed even if they are already unique or are assigned the **dont_touch** attribute. The top-level design is not renamed.

-base_name *base_name*

Specifies the base name to be used instead of the original design name for new designs.

-cell *cell_list*

Specifies a list of cells for which unique designs are to be generated. Unique designs are generated even if the referenced design is already unique, or if the **dont_touch** attribute is set on the cell or its reference. The cells specified in *cell_list* must be in the current design. You cannot specify cells at other levels of hierarchy.

-reference *design_name*

Specifies the name of a design that is referenced by cells for which unique designs are to be created. Unique designs are created even if the referenced design is already unique, or if the **dont_touch** attribute is set on the cells or reference. Only cells in the current design that reference the given design are considered.

-new_name *new_design_name*

Used with the **-cell** option to specify the name for a single cell.

-dont_skip_empty_designs

Indicates that unique designs need to be created even for black box designs. Without this option, uniquify will not modify black box designs.

DESCRIPTION

The **uniquify** command removes multiply-instantiated hierarchy in the current design by creating a unique design for each cell instance. The command initiates a search for designs referenced in the hierarchy of the current design and generates new, uniquely-named designs for all instances that have the same name. If the **dont_touch** attribute is set on a cell, reference, or design, a new design is not created for that cell or any cell with that reference or design.

The **uniquify** command links the current design before it executes. If the link fails, **uniquify** aborts and issues an error message.

If a new design is generated, it is copied from the original design, and placed in the same file as the current design. The new design is named according to the **uniquify_naming_style** variable. The default value of this variable is %s_%d, where %s is replaced by the original design name unless **-base_name** is specified, and %d is replaced by the smallest integer that forms a name not used by any other design in memory. The cell reference is updated to use the new design name.

After **uniquify** executes, all designs in the hierarchy of the current design have unique names. However, some names might conflict with designs on disk if the current design is a submodule of another design. In this case, the user must resolve these conflicts before integrating the designs. One way to resolve conflicts is to use the **uniquify** command with different values of the **uniquify_naming_style** variable.

When a cell instance is used with -cell option, then the complete path to that instance is uniquified. ie. All the parent instances are unquified if they are not already unique.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates uniquely-named designs for all cells and designs in the hierarchy of the current design that have non-unique names, unless a cell or reference has the **dont_touch** attribute set.

```
prompt> uniquify
```

In the following example, a new design "ADDER1" is created for cell "U4" in the current design.

```
prompt> uniquify -cell U4 -new_name ADDER1
```

In the following example, new designs are created with the base name "X" for all cells starting with "U" in the current design.

```
prompt> uniquify -cell [get_cells U*] -base_name X
```

The following example forces all designs in the hierarchy of the current design to be renamed using the **uniquify_naming_style** variable.

```
prompt> set uniquify_naming_style "joe_%s_%d"
prompt> uniquify -force
```

The following example uniquifies the instance mid1 and mid1/bot1. Though the argument to uniquify command is mid1/bot1 since the design mid corresponding to mid1 is not unique, mid1 is also uniquified.

```
prompt> uniquify -cell mid1/bot1
```

SEE ALSO

uniquify_fp_mw_cel

Removes multiple-instantiated hierarchy lib cell in the current design or a specified design by creating a unique hierarchy lib cell for each hierarchy cell instance.

SYNTAX

```
status uniquify_fp_mw_cel
[-verbose]
[-store_mim_property cell_instances]
[design_name]
```

Data Types

<i>cell_instances</i>	collection
<i>design_name</i>	string

ARGUMENTS

-verbose

Indicates to print more information, like the newly created hierarchy lib cell's name.

-store_mim_property *cell_instances*

Indicates to store a "multi instantiated module" (MIM) property on the user specified cell instances during uniquify. Cells with this property will be treated as MIM in Virtual Flat (VF) MIM Design Planning (DP) Flow while actually it has been uniquified.

design_name

Specifies the name of the design in which uniquification is to be performed. If no design is specified, this command tries to find the current design and performs. If specified, this command opens the design first.

DESCRIPTION

uniquify_fp_mw_cel removes multiply-instantiated hierarchy lib cell in the current design or the specified design by creating a unique hierarchy lib cell for each hierarchy cell instance.

If a new hierarchy lib cell is generated, it is copied from the original one, and placed in the same file as the current design. The new hierarchy lib cell is named in a simple %s_%d format, where %s is replaced by the original hierarchy lib cell name and %d is replaced by the smallest integer that forms a name not used by any other hierarchy lib cell in memory. The cell reference is updated to use the new lib cell name.

After **uniquify_fp_mw_cel** executes, all hierarchy lib cell in the hierarchy of the current design have unique names.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates uniquely-named hierarchy lib cell for all hierarchy cell instances in the hierarchy of the newly created design from read_verilog command.

```
prompt> link
Error: Design is not uniquified. (MWDC-101)
Error: Multiply-
instantiated Hierarchical Cell Master 'sub1' (one instance is
'C1'). (MWDC-043)
    Designs should be uniquified before loading them in IC Compiler.
0
prompt> uniquify_fp_mw_cel CORE
1
prompt> link
1
```

In the following example, an existing design is opened for the uniquify_fp_mw_cel command.

```
prompt> open_mw_cel top -lib design
{top}
prompt> uniquify_fp_mw_cel
1
prompt> save_mw_cel
Information: Saved design named top. (UIG-5)
1
```

The following example uniquified the current design and store MIM property for instance A and B.

```
prompt> report_mim
{A B C D E}
prompt> uniquify_fp_mw_cel -store_mim_property {A B}
1
prompt> report_mim
{A B}
```

SEE ALSO

`open_mw_lib(2)`
`open_mw_cel(2)`
`save_mw_cel(2)`
`current_mw_cel(2)`
`report_mim(2)`

unset_hierarchy_color

Removes colors set on leaf cells.

SYNTAX

```
status unset_hierarchy_color
[collection1]
```

Data Types

collection1 collection

ARGUMENTS

collection1

Specifies a collection of objects. Colors set on all leaf cells descended from a hierarchical cell in the collection will be removed

DESCRIPTION

If *collection1* is specified, this command removes the colors set on all leaf cells descended from a hierarchical cell in the collection. Otherwise the commands will remove colors on all leaf cells in the current design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

`set_hierarchy_color(2)`

unset_power_guide

Unsets an existing power guide to be just like an exclusive movebound.

SYNTAX

```
unset_power_guide
[power_guide_list]
```

Data Types

power_guide_list collection

ARGUMENTS

power_guide_list
Unsets the selected power guides.

DESCRIPTION

This command unsets the given power guides. If no specific name is given, all existing power guides will be unset. They will be in design just like an exclusive movebound.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the flow of the **unset_power_guide** command. In it, if the given power guide AO_WELL exists in the design it will be unset.

```
prompt> unset_power_guide AO_WELL
```

SEE ALSO

`create_bounds(2)`
`create_voltage_area(2)`
`report_power_guide(2)`
`set_power_guide(2)`

unsuppress_message

Enables printing of one or more suppressed informational or suppressed warning messages.

SYNTAX

```
string unsuppress_message
[messages]
```

Data Types

messages list

ARGUMENTS

messages
A list of messages to enable.

DESCRIPTION

The **unsuppress_message** command provides a mechanism to re-enable the printing of messages which have been suppressed using **suppress_message**. You can suppress only informational and warning messages, so the **unsuppress_message** command is only useful for informational and warning messages. The result of **unsuppress_message** is always the empty string.

You can suppress a given message more than once. So, you must unsuppress a message as many times as it was suppressed in order to enable it. The **print_suppressed_messages** command displays currently suppressed messages.

EXAMPLES

When the argument to the **unalias** command does not match any existing aliases, the CMD-029 warning message displays. This example shows how to re-enable the suppressed CMD-029 message. Assume that there are no aliases beginning with 'q'.

```
prompt> unalias q*
prompt> unsuppress_message CMD-029
prompt> unalias q*
Warning: no aliases matched 'q*' (CMD-029)
```

SEE ALSO

print_suppressed_messages(2)
suppress_message(2)

update_bounds

Updates an existing bound by adding or removing objects. The bound should be of type move bound.

SYNTAX

```
int update_bounds
[-name bound_name]
[-bound bound_object]
[-add]
[-remove]
cell_list
```

ARGUMENTS

-name *bound_name*

Specifies name of the bound. The bound should be a move bound.

-bound *bound_object*

Specifies the bound object. The bound object can be specified using the *get_bounds* command. You cannot specify more than one bound object.

-add

Specifies that the bound will be updated by adding cells.

-remove

Specifies that the bound will be updated by removing cells.

cell_list

Specifies list of cells to be attached to the bound. If a cell is a hierarchical cell, the bound is also applied to all cells in the subdesigns.

DESCRIPTION

The *update_bounds* command enables you to add or remove cells from an existing move bound. This command does not work with group bounds. You can change the floorplan by adding cells within the move bound or readjust the utilization by removing cells from the move bound. If you add new objects to an existing move bound, the placer honors them during coarse placement. When objects are removed from a move bound, the placer assumes that the objects are no longer constrained by placement bounds. When adding objects, an error occurs if the specified objects are already in a move bound. Similarly for removing objects from move bound, an error occurs if the objects do not belong to the same move bound.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a bound of name "foo" (using the `create_bounds` command), then adds some cells to the bound "foo", and then removes a cell from the same bound object.

```
prompt> create_bounds -name "foo" -coord {100 100 200 200} INSTN_1fp
prompt> update_bounds -name "foo" -add {INSTN_2 INSTN_3}
prompt> update_bounds -bound [get_bounds foo] -remove INSTN_3
```

SEE ALSO

`create_bounds(2)`
`remove_bounds(2)`
`report_bounds(2)`
`get_bounds(2)`

update_clock_latency

Updates the latencies of real and virtual clock objects after clock tree synthesis.

SYNTAX

```
status update_clock_latency
```

ARGUMENTS

This command has no arguments.

DESCRIPTION

This command updates the latencies of real and virtual clock objects after clock tree synthesis. If the **set_latency_adjustment_options** command is used before using the **clock_opt** or before clock tree synthesis, then those directives are used during the update. If no directives are given, then only the latencies of real clock objects are updated. The update mechanism uses the insertion delay (median of the clock arrival times at the clock sinks) of the constructed clock tree to execute a **set_clock_latency** command under the hood on the clock object.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following example shows the use of the command.

```
prompt> update_clock_latency
```

SEE ALSO

```
set_latency_adjustment_options(2)
```

update_flip_chip_pin_locations

Updates the flip chip bump I/O pin locations for timing purposes.

SYNTAX

```
status_value update_flip_chip_pin_locations
```

ARGUMENTS

No arguments needed, the command operates on the current design.

DESCRIPTION

This command updates the I/O pin location to follow the location of the corresponding flip chip bump. This is needed when flip chip bump cells have changed locations and their associated I/O pin locations need to follow for proper timing analysis. If bump locations are changed by place_flip_chip_array or place_flip_chip_ring commands, the I/O pin locations will be automatically adjusted and there is no need to use this command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command updates the I/O pin locations based on the current flip chip bump location:

```
prompt> update_flip_chip_pin_locations  
1
```

SEE ALSO

[place_flip_chip_array\(2\)](#)
[place_flip_chip_ring\(2\)](#)

update_lib

Reads in a specified library file and uses it to update an existing technology, synthetic, or symbol library.

SYNTAX

```
int update_lib
[-overwrite] [-permanent] library_name file_name [-no_warnings]
```

Data Types

<i>library_name</i>	string
<i>file_name</i>	string

ARGUMENTS

-overwrite

Indicates that a group declared in *file_name* is to overwrite any group in *library_name* that has the same name. Only groups added by **update_lib** or **model** can be overwritten. If **-force** is specified, some library-level groups(wire_load, power_supply and operating_conditions) included in the original library can be modified. The other groups included in the original library and groups added with **-permanent** cannot be modified.

-permanent

Indicates that groups declared in *file_name* are to be stored in the library in such a way that they cannot be overwritten.

library_name

Specifies the name of the library to be updated. The library must be resident in memory.

file_name

Specifies the name of the file in which one or more new groups are listed. The syntax of this file is the same as that expected by **read_lib**, except that the file contains only library level groups without the library() {} group definition.

-no_warnings

Indicates that all messages of severity 'warning' are to be suppressed. The default is to issue all warning messages. Warning messages can identify serious library problems; use this flag sparingly.

DESCRIPTION

Reads in a library file and adds the groups declared in that file to the library specified. Groups are added to the library as if entered at the end of the original text of the library.

Only library-level group statements are added to a library. Library level functions or attributes are not accepted(some library-level attributes can be an exception, as

described in the "-force" section).

The library can be a technology, symbol, or synthetic library. Only groups normally found in a library of that type are accepted. For example, you cannot add a symbol group to a technology library. For technology libraries, the delay model and technology associated with the original library must be the same used by new group(s).

If Library Compiler finds any errors while processing a group, it does not add that group to the library. Legal groups are added. The update operation does not fail if there are illegal groups intermixed with legal groups.

If you update a library with a wire_load group describing a wire load model in use by the current design, the wire load model of the current design is reset.

library_name can have a simple or a complex filename. A simple filename has no directory specification, which in UNIX means that it does not contain a "/" (slash). Simple filenames such as **test.lib** or **library.db** must be found in a directory listed in the **search_path**.

A complex filename has a directory specification, which in UNIX means that it contains a slash. Relative or complex filenames such as **./test.lib**, or~synopsys/dc/test.lib are not included in the **search_path**.

For details on library file syntax, refer to the *Library Compiler Reference Manual*. If you do not have a Library Compiler License, function statements and state information are ignored when you attempt to update technology library files. You do not need a Library Compiler License to update symbol library files.

Do not use **update_lib** on the synthetic library **standard.sldb**, because its parts are licensed differently from user parts.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, the library file **add_ms.lib**, which contains technology information in Synopsys technology library entry format, is added to the library **cmos**:

```
prompt> update_lib cmos add_ms.lib
```

In the following example, the library file **new_wire_load.lib**, which contains a new **wire_load** group for a technology library, is added to the library **cmos**. Any **wire_load**(s) in the library that have identical names are overwritten if they are not permanent groups. In addition, all warning messages are suppressed with the -no_warnings flag.

```
prompt> update_lib -overwrite cmos new_wire_load.lib -no_warnings
```

In the following example, the library file **ramgen.lib**, which contains a black-box cell description of a RAM cell, is added to the library **cmos**. The **-permanent** flag indicates that the new cell cannot be overwritten.

```
prompt> update_lib -permanent cmos ramgen.lib
```

SEE ALSO

[write_lib\(2\)](#)

update_physical_bus

Updates an existing physical bus by adding or removing objects.

SYNTAX

```
status update_physical_bus
physical_bus
-add net_list | -remove net_list
[-position position]
[-sort {ascending | descending | none}]
[-delimiter delimiter]
[-right_precedence]
[-quiet]
```

Data Types

<i>physical_bus</i>	string
<i>net_list</i>	list
<i>position</i>	integer
<i>delimiter</i>	string

ARGUMENTS

physical_bus

Specifies a physical bus object. You can specify name of a physical bus object or a collection containing a physical bus.

-add net_list

Specifies a list of nets to be added into the specified physical bus.

The **-add** and **-remove** options are mutually exclusive. You must specify one, but not both.

-remove net_list

Specifies a list of nets to be removed from the specified physical bus.

The **-add** and **-remove** options are mutually exclusive. You must specify one, but not both.

-position position

Specifies the position after which the specified nets will be added.

This option is effective with the option **-add** specified.

If you don't specify *position*, nets will be appended to the end.

-sort {ascending | descending | none}

Specifies the sort mode. The valid values are: **ascending**, **descending**, and **none**.

This option is effective with the option **-add** specified.

If you specify *-sort ascending*, nets will be sorted by their names alphanumerically, from lowest to highest. If you specify *-sort descending*, nets will be sorted by their names alphanumerically, from highest to lowest.

If you specify *-sort none*, no sort will be applied.

By default *sort_mode* is *none*.

-delimiter delimiter
 Specifies the delimiter characters to use for the names of nets.
 This option is effective with the option **-add** specified.
 The valid values of *delimiter* are: **[]**, **{}**, **<>**, **()**, **_** and **::**. By default *delimiter* is **[]**.
 When nets are sorted, characters inside *delimiter* will be regarded as index.
 For example, Two nets Net[2] and Net[10] with **-sort ascending**, Net[2] will be in front of Net[10].

-right_precedence
 Indicates that sorting of index inside *delimiter* is from right to left. By default the order is from left to right.
 This option is effective with the option **-add** specified.
 For example, there are six nets with **-sort ascending** and no option **-right_precedence**, the ordered list will be:
Net[0][1], Net[0][2], Net[1][1], Net[1][2], Net[2][1], Net[2][2],
 While with **-sort ascending** and option **-right_precedence**, the ordered list will be:
Net[0][1], Net[1][1], Net[2][1], Net[0][2], Net[1][2], Net[2][2],

-quiet
 Suppresses warning and error messages. Syntax error messages are not suppressed.

DESCRIPTION

The **update_physical_bus** command enables you to add or remove nets from an existing physical bus.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a physical bus of name "bus1", removes two nets from it, adds other two nets to it, and then use command **get_nets -of_object \$bus1** to see the elements in the physical bus.

```
prompt> set bus1 [create_physical_bus bus1 -sort ascending \
-nets [get_nets UPC_DATA*]]fp
{bus1}

prompt> update_physical_bus $bus1 -remove \
[get_nets {UPC_DATA[2] UPC_DATA[5]}]
1

prompt> update_physical_bus bus1 -position 0 -add \
[get_nets {Y[0] Y[3]}] -sort descending
```

```
1
prompt> get_nets -of_object $bus1
{Y[3] Y[0] UPC_DATA[0] UPC_DATA[1] UPC_DATA[3] UPC_DATA[4] UPC_DATA[6] UPC_DATA[7]
UPC_DATA[8] UPC_DATA[9] UPC_DATA[10] UPC_DATA[11]}
```

SEE ALSO

`create_physical_bus(2)`
`get_nets(2)`
`get_physical_buses(2)`
`remove_physical_bus(2)`
`report_physical_bus(2)`

update_timing

Updates timing information on the current design.

SYNTAX

```
int update_timing
```

ARGUMENTS

None.

DESCRIPTION

Updates timing for the current design. Timing information is obsoleted when environmental information, such as arrival times or loads, is changed. The **update_timing** command is used to update this information after these changes are made.

Timing information is automatically updated in the current design when **compile** or **translate** is used or when reports that display timing information are used. So, for most cases, the **update_timing** command is not needed. However, there are instances when timing might not be current (such as if **set_attribute** is incorrectly used instead of **set_drive** to set a drive value).

Note that this command does not automatically identify and define clocks in the design. These should be defined by using the **create_clock** command.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

This example updates timing for the current design.

```
prompt> update_timing
```

SEE ALSO

```
create_clock(2)
set_drive(2)
current_design(3)
```

update_voltage_area

Updates an existing voltage area by adding or removing logical hierarchies.

SYNTAX

```
int update_voltage_area
-voltage_area list
[-add]
[-remove]
[-guard_band_x int]
[-guard_band_y int]
[modules]
```

ARGUMENTS

-voltage_area list

Specifies the voltage areas. The patterns can be a collection handle of voltages or name patterns:

If more than one voltage area object is specified, this command will report error. This option must be specified.

-add

Specifies that the voltage area will be updated by adding hierarchical cells. This option is exclusive with -remove. This option must be used with modules.

-remove

Specifies that the voltage area will be updated by removing hierarchical cells.

This option is exclusive with -add. This option must be used with modules.

-guard_band_x int

Specifies the horizontal margin or the left margin and the right margin of the voltage area where you want to change the guard band.

-guard_band_y int

Specifies the vertical margin or the top margin and the bottom margin of the voltage area where you want to change the guard band.

modules

Specifies list of cells to be attached with the voltage area. This option must be used with -add or -remove.

DESCRIPTION

update_voltage_area command allows the user to keep adding or removing logical hierarchies in the existing voltage area.

If you try to add a hierarchical cell on which another voltage area is defined, the command will fail.

If you try to remove a hierarchical cell on which current voltage area isn't

defined, the command will fail.

When a hierarchical cell is removed from specified voltage area, its all leaf child cells will be reassociated with the its nearest ascent's voltage area, if any. If none of its ascents is associated with any voltage area, or it doesn't have any ascents, its all leaf child cells will be free.

You can update the value of the guard band around the voltage area using the **-guard_band_x** option and the **guard_band_y** option. The tool considers the guard bands as placement keepouts. Use guard bands as a method to prevent substrate leakage between voltage areas.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example updates the voltage area named "foo" by first adding cells and then removing a cell from the same voltage area.

```
prompt> create_voltage_area -coor {10 10 100 80} -name foo \
      [get_cells INSTN_1]
{foo}
prompt> update_voltage_area -voltage_area foo -add INSTN_2
1
prompt> update_voltage_area -voltage_area [get_voltage_area foo] \
      -remove INSTN_2
1
```

The following example shows error case by adding a hierarchical cell on which another voltage area is defined, and by removing a hierarchical cell on which the current voltage area isn't defined.

```
prompt> create_voltage_area -coor {10 10 50 50} -name VA1 \
      [get_cells INSTN_1]
{VA1}
prompt> create_voltage_area -coor {100 100 180 160} -name VA2 \
      [get_cells INSTN_2]
{VA2}
prompt> update_voltage_area -voltage_area VA1 -add INSTN_2
ERROR : hierarchical cell 'INSTN_2' already has voltage area.
prompt> update_voltage_area -voltage_area VA1 -remove INSTN_1/A1
ERROR : cell 'INSTN_1/A1' doesn't belong to the current voltage area.
```

SEE ALSO

`create_voltage_area(2)`
`remove_voltage_area(2)`
`report_voltage_area(2)`
`get_voltage_areas(2)`

verify_drc

Detects DRC violations.

SYNTAX

```
integer verify_drc
[-error_cell cell_name]
[-dir runset_directory]
[-ignore_width]
[-ignore_spacing]
[-ignore_area]
[-ignore_enclosed_area]
[-ignore_density]
[-ignore_min_edge_length]
[-check_via_size]
[-ignore_via_spacing]
[-ignore_adjacent_via]
[-ignore_min_via_number]
[-ignore_stack_level]
[-ignore_stackable]
[-check_enclosure]
[-check_end_of_line]
[-check_via_farm]
[-check_fat_poly_contact]
[-check_blockage]
[-ignore_child_cell]
[-read_cell_view]
[-check_cross_hier_short_only]
[-write_hercules_runset_only]
[-selected_area {{llx1 lly1} {urx1 ury1} ...}]
[-excluded_area {{llx1 lly1} {urx1 ury1} ...}]
[-exclude_by_cell_name {collection_of_master_cells}]
[-offset_distance value]
```

Data Types

<i>cell_name</i>	string
<i>runset_directory</i>	string
<i>llx1</i>	float
<i>lly1</i>	float
<i>urx1</i>	float
<i>ury1</i>	float
<i>collection_of_master_cells</i>	collection
<i>value</i>	float

ARGUMENTS

-error_cell *cell_name*

Name to assign to the error cell. If the option is missing, <current_cell_name>_adrc.err is used by default.

```
-dir runset_directory
    Name of the Hercules runset directory. Default: adrc.

-ignore_width
    Set this option to skip checking the minimum and maximum width rules. These
    rules are checked by default.

-ignore_spacing
    Set this option to skip checking all rules related to spacing, including basic
    spacing, same-net spacing (notch), basic fat spacing, fat table spacing, the
    fat table parallel length rule (mode 0/1), and the fat table extension range
    rule (mode 0/1). These rules are checked by default.

-ignore_area
    Set this option to skip checking the minimum area rule. This rule is checked
    by default.

-ignore_enclosed_area
    Set this option to skip checking the basic minimum enclosed area rule and the
    fat table minimum enclosed area rule. These rules are checked by default.

-ignore_density
    Set this option to skip checking the metal density rule. This rule is checked
    by default. You should have a Hercules license to check the metal density
    rule.

-ignore_min_edge_length
    Set this option to skip checking the minimum-number-of-consecutive-short-
    edge rule. This rule is checked by default.

-check_via_size
    Set this option to check the via size rule. Usually, via sizes on the same
    layer are uniform, so it is not necessary to activate this option in most
    cases. These rules are not checked by default.

-ignore_via_spacing
    Set this option to skip checking the via spacing rules, including the basic
    via spacing rule, the basic fat contact rule, the fat contact table spacing
    rule, and the fat contact table extension range rule. These rules are checked
    by default.

-ignore_adjacent_via
    Set this option to skip checking the maximum-number-of-adjacent-via rule and
    the enclosed via rule. These rules are checked by default.

-ignore_min_via_number
    Set this option to skip checking the minimum-number-of-via rule defined in
    the fat contact table (including the extension range). These rules are
    checked by default.

-ignore_stack_level
    Set this option to skip checking the maximum-number-of-stack-layer rule. This
    rule is checked by default.
```

-ignore_stackable
Set this option to skip checking the stack via rule. This rule is checked by default.

-check_enclosure
Set this option to check the via enclosure rule. Usually, this rule is guaranteed by the definition of vias, so it is not necessary to activate this option in most cases. These rules are not checked by default.

-check_end_of_line
Set this option to check the end-of-line rule. Usually, this rule is guaranteed by the via enclosure rule, so it is not necessary to activate this option in most cases. These rules are not checked by default.

-check_via_farm
Set this option to check the via farm (via array) rule. This rule specifies the via array size and the spacing between two via arrays. These rules are not checked by default.

-check_fat_poly_contact
Set this option to check the fat poly contact rule. This rule specifies the thresholds that the router uses to determine whether a metal wire is fat. The tool avoids creating new fat wires of width greater than the threshold when connecting to a pin. These rules are not checked by default.

-check_blockage
Set this option to check the blockages on the metal layers. When this option is off, all blockages are ignored. When it is on, the blockages on the metal layers are treated as regular metal wires, and the blockages on the metal_blockage layer are treated as thin blockages. The option is off (blockages are ignored) by default.

-ignore_child_cell
Set this option to skip the violations inside or among all child cells. This option is off by default.

-read_cell_view
Set this option to read child cells from the cell view. If the cell view for a child cannot be found, the command stops. When this option is off (default), the child cells are read from the FRAM view. If the FRAM view for a child cell cannot be found, the command ignores it and continues.

-check_cross_hier_short_only
Set this option to check only overlapping errors between top level wires and metal objects, like wires, vias, blockages, routeguides and pins inside a FRAM view, including both Macros and Standard Cells. This option is useful for a quick violation check after manual editing. This option is off by default.

-write_hercules_runset_only
Set this option to dump the runset to the directory, specified in "dir" without running Hercules. You can modify and run the runset ev_engine adrc.ev. This option is off by default.

```

-selected_area {{llx1 lly1} {urx1 ury1} ...}
    Specify either an area or areas to perform design rule checking. An area is
    a collection of two points that specify the lower-left and upper-right
    corners.

-excluded_area {{llx1 lly1} {urx1 ury1} ...}
    Specify either an area or areas to exclude the design rule checking.

-exclude_by_cell_name {collection_of_master_cells}
    Specify the cell master name(s) to exclude the design rule checking.

-offset_distance value
    Specify a value to extend or shrink the checking areas (or cell boundary),
    the value should be more than 0. The value can be provided by user or
    automatically calculated (if no value is specified). For the automatic
    calculated case, it must get the largest possible checking value defined in
    the technology file. For the selected_area case, it will extend a value
    outside the checking area or cell boundary. On the other hand, for
    excluded_area or exclude_by_cell_name case, it will shrink a value inside the
    checking area or cell boundary.

```

DESCRIPTION

The **verify_drc** command detects design rule violations. It automatically generates design rule checking (DRC) runsets for the Hercules tool, then calls Hercules to check the violations. For a more detailed description about Hercules, please refer to the *Hercules Reference Manual*.

For information about the design rules and the technology file attributes that define them, see the *Milkyway Data Preparation User Guide*.

All options are optional.

NOTES

For the options -exclude_by_cell_name and -offset_distance, any data from cells at higher levels in the hierarchy that are within the selected boundary of the cell will be excluded as well.

The **verify_drc** command does not support macro metal density from LEF or PLIB when the option -read_cell_view is used.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example is to run command **verify_drc** with customized error cell name.

```
prompt> verify_drc -error_cell my_err_cell
```

The following example is to run command **verify_drc** with two selected areas (50.17 103.85) (105.29 147.16), (144.3 49.09) (184.02 97.05), with the offset distance 0.6.

```
prompt> verify_drc -selected_area {{50.17 103.85} {105.29 147.16} \  
{144.3 49.09} {184.02 97.05}} -offset_distance 0.6
```

The following example is to run command **verify_drc** with a excluded area (50.17 103.85) (105.29 147.16), and the offset distance is automatically calculated.

```
prompt> verify_drc -excluded_area {{50.17 103.85} {105.29 147.16}}
```

The following example is to run command **verify_drc** with the excluding master cells A and B that do not need to be verified, with the offset distance 0.

```
prompt> verify_drc -exclude_by_cell_name {A B} -offset_distance 0
```

SEE ALSO

[verify_lvs\(2\)](#)
[verify_route\(2\)](#)
[count_drcViolations\(2\)](#)

verify_lvs

Checks for inconsistencies between the schematic and physical layout of the current design. Violations discovered by the check are written to a design error view (error cell). You can browse the error view with the IC Compiler Error Browser.

SYNTAX

```
status verify_lvs
[-error_cell cell_name]
[-ignore_floating_port]
[-ignore_floating_net]
[-ignore_short]
[-ignore_open]
[-ignore_eeq_pin]
[-ignore_min_area]
[-use_notch_gap_fill_cell]
[-ignore_blockage_overlap]
[-check_single_pin_net_for_floating_port]
[-check_floating_port_on_null_net]
[-ignore_floating_metal_fill_net]
[-max_error ]
[-check_single_pin_net_for_floating_net]
[-check_short_locator]
[-check_open_locator]
```

ARGUMENTS

-error_cell *cell_name*

Specifies the name to assign to the design error view.
By default, the name is *current_cell_name_adrc.err*.

-ignore_floating_port

Do not check for ports that are not connected to a net.

-ignore_floating_net

Do not check for nets that are not connected to anything.

-ignore_short

Do not check for shorts between nets.

-ignore_open

Do not check for open nets.

-ignore_eeq_pin

Do not check for pins of different electrical equivalent classes that are connected together.

-ignore_min_area

Do not check for metal that is less than the minimum area.

-use_notch_gap_fill_cell

Include notch gap filler cells in the checking. By default, these cells are

not checked.

-ignore_blockage_overlap
Do not check for cell overlaps.

-check_single_pin_net_for_floating_port
Check for pins that are not connected to top-level metal. By default, this rule is not checked.

-ignore_floating_metal_fill_net
Do not check the floating metal created by metal fill.

-max_error
Specifies the maximum number of errors reported in this LVS run.
By default, there is no limit to the number of reported errors.

-check_single_pin_net_for_floating_net
Check for top-level metal that connect to only one pin. By default, this rule is not checked.

-check_short_locator
Report the detailed short locations.
By default, **verify_lvs** reports only which nets are shorted with each others and the reported short locations are the shapes for the nets containing the short.
When you specify this option, **verify_lvs** reports the exact short locations. A short type error is written for each short in a net and the reported short locations are the bounding boxes around the shorted areas. There is an additional runtime cost for computing the detailed short locations.

-check_open_locator
Report the detailed open pair locations.
By default, **verify_lvs** reports the nets with any number of opens, but not the potential connection endpoints. The open nets are shown as open type errors. When you specify this option, **verify_lvs** reports each open in a net as a pair of potential connection endpoints. The opens are shown as open locator type errors. There is an additional runtime cost for computing the detailed open pair locations.

DESCRIPTION

The **verify_lvs** command detects schematic versus physical layout errors.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **verify_lvs** command and generates an error cell named my_err_cell.

```
prompt> verify_lvs -error_cell my_err_cell
```

SEE ALSO

verify_pg_nets

Checks whether or not all power and ground pins of standard cells, macro cells and pad cells are connected to the corresponding power and ground nets.

SYNTAX

```
integer verify_pg_nets
[-error_cell cell_name]
[-std_cell_pin_connection ( check | ignore)]
[-macro_pin_connection ( at_least_one | all | ignore )]
[-pad_pin_connection ( at_least_one | all | ignore )]
```

ARGUMENTS

```
-error_cell cell_name
    Specifies the name of the error cell. If this option is skipped,
    <top_cell_name>.err is used as default.

-std_cell_pin_connection ( check | ignore)
    Specifies whether to check (which is a default) or ignore checking if each
    standard cell connects to power and ground.

-macro_pin_connection ( at_least_one | all | ignore)
    Specifies to check whether and how macro cells connect to power and ground.
    at_least_one (which is a default) checks whether each macro cell has at least
    one pin connected to power and ground. all checks whether each macro cell has
    all its power and ground pins connected to power and ground. ignore does not
    check whether macro cells connect to power and ground.

-pad_pin_connection ( at_least_one | all | ignore)
    Specifies to check whether and how pads connect to power and ground.
    at_least_one (which is a default) checks whether each pad has at least one
    pin connected to power and ground. all checks whether each pad has all its
    power and ground pins connected to power and ground. ignore does not check
    whether pads connect to power and ground, and does a check for floating shapes
    on all power and ground nets, and flags the violations you have reported.
```

DESCRIPTION

The **verify_pg_nets** command checks whether or not all power and ground pins of standard cells, macro cells and pad cells are connected to the corresponding power and ground nets. The verify_pg_nets command also checks each power and ground net for floating shapes, and creates an error cell that you can view the errors. Checks power and ground pins only. Tie-up and tie-down pins, which are signal pins, are not checked. Use the connect_pg_nets command to specify port-to-net connections for power and ground nets if they are not part of the netlist.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

To use default <top_cell_name>.err cell, not check standard cell connections, check all macro pin connections, and check at least one pin of pad cells connection to power and ground (used as default here), enter

```
verify_pg_nets -std_cell_pin_connection ignore -macro_pin_connection all
```

SEE ALSO

```
create_rectangular_rings(2)
create_power_straps(2)
create_preroute_vias(2)
preroute_instances(2)
preroute_standard_cells(2)
```

verify_route

Verifies and reports DRC violations and opens

SYNTAX

```
status verify_route
[-nets {collection_of_nets}]
[-no_drc]
[-noOpens]
[-antenna]
[-top_layer_probe_constraints]
[-num_cpu int]
[-bounding_box {{llx lly} {urx ury}}]
[-output file_name]
```

Data Types

<i>collection_of_nets</i>	collection
<i>int</i>	integer
<i>llx</i>	float
<i>lly</i>	float
<i>urx</i>	float
<i>ury</i>	float
<i>file_name</i>	string

ARGUMENTS

```
-nets {collection_of_nets}
      Specifies the nets to report the opens only violations. If you specify more
      than one net in a collection they must be separated by a space. This option
      is off by default.

-no_drc
      Ignored drc violations in detail routed design. This option is off by default.

-noOpens
      Ignored opens in detail routed design. This option is off by default.

-antenna
      Check and report for Charge-Collecting Antenna in a routed design. This
      option is off by default.

-top_layer_probe_constraints
      Check and report for Top-Layer Probe Constraints in a routed design. This
      option is off by default.

-num_cpu int
      Selected this option to use the distributed routing feature, that is, to run
      the command parallel on different CPUs and machines. Enter the number of CPUs
      that the command uses. If it is less than 1, this distributed routing feature
      is disabled and uses the single CPU, which is default value. If it is >= 1,
      the network has to be setup properly to be able to run the command parallel
```

```
before selecting this option. The upper limit is 63.  
  
-bounding_box {{llx lly} {urx ury}}  
    Specify an area to perform design rule checking. An area is a collection of  
    two points that specify the lower-left and upper-right corners. This option  
    is off by default.  
  
-output file_name  
    Output drc violations into a file. This option is off by default.
```

DESCRIPTION

Verifies, checks and reports the following about a routed design: DRC Violations, Opens, Charge-Collecting Antenna violations, and Top-Layer Probe Constraints.

If -nets option is selected, **verify_route** checks only Opens of the specified nets, and all other arguments are ignored.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports drc violations and opens by running the command on one CPU.

```
prompt> verify_route
```

The following example ignored drc violations in report. The job is distributed on two CPUs and run in parallel.

```
prompt> verify_route -no_drc -num_cpu 2
```

The following example reports opens for nets N1, N2, and N3.

```
prompt> verify_route -nets {N1 N2 N3}
```

The following example checks DRC violations within the bounding box (40.27 98.85) (135.39 167.16).

```
prompt> verify_route -bounding_box {{40.27 98.85} {135.39 167.16}}
```

The following example dumps drc violations to the file drc.sum.

```
prompt> verify_route -output drc.sum
```

SEE ALSO

count_drc_violations(2)

verify_zrt_route

Verifies and reports design rule constraint (DRC) violations, net opens, antenna rule violations, and voltage area rule violations.

SYNTAX

```
status verify_zrt_route
[-nets {collection_of_nets}]
[-open_net true | false]
[-report_all_open_nets true | false]
[-drc true | false]
[-antenna true | false]
[-voltage_area true | false]
[-check_from_user_shapes true | false]
```

Data Types

collection_of_nets collection or list

ARGUMENTS

-nets {collection_of_nets}

Specifies the nets to verify. If you specify this option, the command does not check for DRC violations, regardless of the setting of the **-drc** option. By default, all nets are verified.

-open_net true | false

If true (the default), the command checks for open nets in the design.

-report_all_open_nets true | false

If false (the default), the command reports a maximum of 200 open nets when checking for open nets.

-drc true | false

If true (the default), the command checks for design rule violations on the specified nets.

-antenna true | false

If true (the default), the command checks for charge-collecting antenna rule violations on the specified nets.

-voltage_area true | false

If true (the default), the command checks for voltage-area rule violations on the specified nets.

-check_from_user_shapes true | false

If true, the command checks DRC violations for user-created shapes, as well as routing shapes. The default is false.

DESCRIPTION

Verifies, checks, and reports the following rules for a routed design: DRC violations, open nets, charge-collecting antenna violations, and voltage-area violations.

If you specify the **-nets** option, **verify_zrt_route** checks only for open nets, antenna violations, and voltage-area violations of the specified nets. All other arguments are ignored.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports DRC violations, open nets, antenna violations, and voltage-area violations for all nets in the design.

```
prompt> verify_zrt_route
```

The following example checks for open nets, antenna violations, and voltage-area violations, but not for DRC violations.

```
prompt> verify_zrt_route -drc false
```

The following example checks for open nets, antenna violations, and voltage-area violations for nets N1, N2, and N3. Note that these rules are checked by default, and DRC violations are not checked.

```
prompt> verify_zrt_route -nets {N1 N2 N3}
```

The following example reports only antenna and voltage-area violations for nets N1 and N2.

```
prompt> verify_zrt_route -nets {N1 N2} -open_net false
```

SEE ALSO

[route_zrt_detail\(2\)](#)

which

Locates a file and displays its pathname.

SYNTAX

```
string which
filename_list
```

Data Types

```
filename_list      list
```

ARGUMENTS

```
filename_list
    List of files to locate.
```

DESCRIPTION

Displays the location of the specified files. This command uses the search_path to find the location of the files. This command can be a useful prelude to read_db or link_design, because it shows how these commands expand filenames. The **which** command can be used to verify that a file exists in the system.

If an absolute pathname is given, the command searches for the file in the given path and returns the full pathname of the file.

EXAMPLES

The following examples are based on the following search_path.

```
prompt> set search_path "/u/foo /u/foo/test"
```

The following command searches for the file name foo1 in the search_path.

```
prompt> which foo1
/u/foo/foo1
```

The following command searches for files foo2, foo3.

```
prompt> which {foo2 foo3}
/u/foo/test/foo2 /u/foo/test/foo3
```

The following command returns the full pathname.

```
prompt> which ~/test/designs/sub_design.db
/u/foo/test/designs/sub_design.db
```

SEE ALSO

`search_path(3)`

widen_zrt_wires

Performs wire widening.

SYNTAX

```
status widen_zrt_wires
[-timing_preserve_nets {collection_of_nets}]
[-timing_preserve_setup_slack_threshold slack_value]
[-timing_preserve_hold_slack_threshold slack_value]
```

Data Types

<i>collection_of_nets</i>	collection or list
<i>slack_value</i>	float

ARGUMENTS

`-timing_preserve_nets {collection_of_nets}`

Specifies the nets to preserve timing on. If you specify this option, the command will consider the specified nets as timing critical and will skip widening on these and the neighboring nets.

`-timing_preserve_setup_slack_threshold slack_value`

Specifies the slack threshold for timing critical nets. If you specify this option, the command will skip widening on all nets with worst setup slack less than or equal to this value and the neighboring nets.

`-timing_preserve_hold_slack_threshold slack_value`

Specifies the slack threshold for timing critical nets. If you specify this option, the command will skip widening on all nets with worst hold slack less than or equal to this value and the neighboring nets.

DESCRIPTION

The **widen_zrt_wires** command performs wire widening. It attempts to widen every wire in the design. The options control the maximum number of search and repair iterations performed after wire widening to resolve any violations.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following command performs wire widening.

```
prompt> widen_zrt_wires
```

SEE ALSO

`route_zrt_detail(2)`

window_stretch

Stretches one or more objects by moving the objects points or edges that are containing within a bounding box

SYNTAX

```
status window_stretch
-delta vector
-rectangle rect
[-keep_placement]
[-keep_pad_to_core_distance]
[-ignore_fixed]
objects
```

Data Types

```
rect          x1 y1 x2 y2
objects       collection
```

ARGUMENTS

```
-delta vector
    Specifies the distance to move the objects points or edges which are inside
    the specified bounding box.

-rectangle rect
    Specifies the bounding box which defines which points or edges of the
    specified objects are moved.

-keep_placement
    This option is effective only when applied to the core or the die. It will
    be ignored if applied on any other object.
    Cells in the core and IO pad cells are re-placed if necessary. The relative
    positions of the cells are not guaranteed to be preserved, although an attempt
    will be made to preserve them as much as possible. Furthermore, the output
    of the re-placement is not legalized. The user needs to explicitly legalize
    the placement using legalize_placement.
    The default is false.

-keep_pad_to_core_distance
    This option is effective only when applied to the core or the die. It will
    be ignored if applied on any other object.
    This maintains the distance between the core and the pad cells and by
    implication the distance between the core and the die, thus forcing changes
    to the core and the die to be made in tandem with each other. If pad cells
    are absent then the core-to-die distance will still be maintained.
    The default is false.

-ignore_fixed
    Normally fixed objects will not be stretched. If this flag is supplied then
    fixed objects will also be stretched.
```

objects
Specifies the objects to be stretched.

DESCRIPTION

This command stretches one or more objects by a specified distance in the x and/or y directions.

For wires and paths, stretching is achieved by moving all points inside the specified bounding box by the specified delta and retaining the position of all points outside the bounding box.

For all other objects, stretching is achieved by moving all edges inside the specified bounding box by the specified delta and retaining the position of all edges outside the bounding box.

See `get_edit_property(2)` man page for more details on which objects can be stretched using the `resizable` property

NOTES

Snapping is done automatically using global snap settings.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example stretches the currently selected objects which are inside the bounding box {100 100 200 200} by 100 units to the right and 200 units above the original object.

```
prompt> set bbox {100 100 200 200}
prompt> set delta {100 200}
prompt> window_stretch -rectangle $bbox -delta $delta [get_selection]
```

SEE ALSO

`resize_objects(2)`
`set_object_snap_type(2)`
`get_object_snap_type(2)`

write

Writes a design netlist or schematic from memory to a file.

SYNTAX

```
status write
[-format output_format]
[-hierarchy]
[-no_implicit]
[-modified]
[-output output_file_name]
[-names_file name_mapping_files]
[-donot_expand_dw]
[-scenarios scenario_list]
[design_list]
[-library library_name]
```

Data Types

<i>output_format</i>	string
<i>output_file_name</i>	string
<i>name_mapping_files</i>	list
<i>scenario_list</i>	list
<i>design_list</i>	list
<i>library_name</i>	string

ARGUMENTS

-format *output_format*
Specifies the output format of the design. Supported output formats and their descriptions are the following:

ddc - Synopsys internal database format (the default format)
vhdl - IEEE Standard VHDL

-hierarchy
Writes all designs in the hierarchy. You can use this option with any other option, If a design hierarchy does not completely link, unresolved design references do not write.

-no_implicit
Indicates not to write (save) the synthetic design hierarchy that is implicitly created during optimization of the design. By default, the command writes designs created in the hierarchy through the use of synthetic libraries, even if you do not use the **-hierarchy** option.

-modified
Writes only the designs that have changed since the last write.

-output *output_file_name*
Specifies a single file into which designs are to be written. By default, the command writes each design into a separate file named *design.suffix*, where

design is the name of each design (a full UNIX path) and *suffix* is the default suffix for the specified format. The default format suffixes and their descriptions are:

.**ddc** - ddc
.vhd - vhdl

-names_file *name_mapping_files*

Lists files for name changes.

-donot_expand_dw

Indicates that DesignWare components are not to be linked. This option is effective only if you have previously run the **insert_dft** command. If you used **insert_dft** to synthesize boundary-scan using DesignWare components, you can use the **-donot_expand_dw** option to avoid auto linking of the DesignWare components, which would otherwise appear in instance statements as modules having no implementation.

-scenarios *scenario_list*

Lists scenarios whose constraints should be included in the output file. This option applies to ddc format only. By default, the command includes all scenarios.

design_list

Lists designs or design files to write. After a design is written, it still exists in memory. To remove a design from memory, use the **remove_design** command. By default, the command lists the current design.

-library *library_name*

Writes the Synopsys database format object to the specified library.

DESCRIPTION

This command outputs designs from memory to disk. If a design is modified in the tool, you must use the **write** command to save the design.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following are examples of saving designs in .ddc format.

The following example shows the most common use of saving designs in .ddc format, which is to write a design to its assigned file.

```
prompt> write {A B C}
Writing to file 'A.ddc'
Writing to file 'B.ddc'
```

```
Writing to file 'C.ddc'
```

The following example shows that all designs saved in .ddc format are written if you specify a design that is one of many designs in a file.

```
prompt> write top
```

```
Writing to file 'top.ddc'
```

The following example shows multiple designs being saved in .ddc format are being written to a single file.

```
prompt> write -output mine.ddc {ADDER MULT16}
```

```
Writing to file 'mine.ddc'
```

The following example shows the use of the **-hierarchy** option. All designs (being saved in .ddc format) in the hierarchy of the specified designs are written.

```
prompt> write -hierarchy top
```

```
Writing to file 'top.ddc'
```

```
Writing to file 'A.ddc'
```

```
Writing to file 'B.ddc'
```

The following example shows another use of the **-hierarchy** option. All designs (being saved in .ddc format) in the hierarchy of the specified designs are written.

```
prompt> write -hierarchy -output ~bill/dc/top.ddc top
```

```
Writing to '~bill/dc/top.ddc'
```

The following example shows the specifying of the default design filename instead of the design name. It writes all designs that reside in a file named top.ddc.

```
prompt> write top.ddc
```

```
Writing to file '/osi4/bill/dc/top.ddc'
```

The following example shows how to resolve an ambiguous file name. You can read more than one design with the same name into memory. To avoid ambiguity, specify the file name when writing the design. You might also have more than one file with the same name in memory (for example, top.ddc and top.ddc). To resolve this conflict, prepend the file name with its full pathname. In the following example, the file name "top.ddc" is ambiguous, and the ambiguity is resolved by using the full pathname.

```
prompt> write top.ddc
```

```
Error: 'top' doesn't specify a unique design
```

```
Please use complete specification: full_file_name:design_name
```

```
prompt> write /osi4/bill/dc/top.ddc
```

```
Writing to file '/osi4/bill/dc/top.ddc'
```

SEE ALSO

`write_verilog(2)`
`view_write_file_suffix(3)`

write_def

Writes the design data of the specified design to a file in DEF format, including the physical layout, netlist, and design constraints.

SYNTAX

```
status write_def
-output output_file_name
[-version 5.3 | 5.4 | 5.5 | 5.6 | 5.7]
[-unit conversion_factor]
[-compressed]
[-rows_tracks_gcells]
[-vias]
[-all_vias]
[-nondefault_rule]
[-lef lef_file_name]
[-regions_groups]
[-components]
[-macro]
[-fixed]
[-placed]
[-pins]
[-blockages]
[-specialnets]
[-notch_gap]
[-pg_metal_fill]
[-nets]
[-routed_nets]
[-diode_pins]
[-floating_metal_fill]
[-scanchain]
[-no_legalize]
[-verbose]
```

Data Types

<i>output_file_name</i>	string
<i>conversion_factor</i>	integer
<i>lef_file_name</i>	string

ARGUMENTS

```
-output output_file_name
        Specifies the name of the output DEF file written by write_def. This is a required argument.

-version 5.3 | 5.4 | 5.5 | 5.6 | 5.7
        Specifies the version of DEF to be written to output DEF file. Valid def_version values are 5.3, 5.4, 5.5 and 5.6. The default is 5.5.

-unit conversion_factor
        Specifies the value used in the DEF UNITS DISTANCE MICRONS statement. Valid
```

values for conversion factor are 100, 200, 1000, 2000, 10000 and 20000. The values 10000 and 20000 are supported in DEF 5.6.

-compressed

Specifies that the DEF file is compressed using gzip format.

-rows_tracks_gcells

Specifies that the ROW, TRACK and GCELLGRID sections are to be included in the output DEF file. It can be combined with options for writing out other DEF sections.

-vias

Specifies that the VIAS section is to be included in the output DEF file. It can be combined with options for writing out other DEF sections.

-all_vias

Specifies that all vias (those present in the design, as well as those present in technology file) are included in the output DEF file. If this option is not specified, only vias present within the design are written out.

-nondefault_rule

Specifies that the NONDEFAULTRULES section is to be included in the output DEF file. The option only works for DEF output of version 5.6 because the NONDEFAULTRULES syntax is not supported in DEF 5.5 or lower DEF version.

-lef lef_file_name

Specifies that rotated vias and design-specified nondefault rule are to be written to the specified LEF file.

-regions_groups

Specifies that the REGIONS and GROUPS sections are to be included in the output DEF file. It can be combined with options for writing out other DEF sections.

-components

Specifies that the COMPONENTS section is to be included in the output DEF file. It can be combined with options for writing out other DEF sections.

-macro

Specifies that only macro cells are to be included in the COMPONENTS section. If this option is not specified, standard and macro cells are included in the COMPONENTS section.

-fixed

Specifies that only fixed cells are to be included in the COMPONENTS section. If this option is not specified, fixed, cover, placed, and unplaced cells are included in the COMPONENTS section.

-placed

Specifies that only fixed and placed cells are to be included in the COMPONENTS section. If this option is not specified, fixed, cover, placed, and unplaced cells are included in the COMPONENTS section.

-pins

Specifies that the PINS section is to be included in the output DEF file. It

can be combined with options for writing out other DEF sections.

-blockages

Specifies that the BLOCKAGES section is to be included in the output DEF file. It can be combined with options for writing out other DEF sections.

-specialnets

Specifies that the SPECIALNETS section is to be included in the output DEF file. To include notch/gap and P/G metal fills as well, use "-notch_gap" and "-pg_metal_fill". It can be combined with options for writing out other DEF sections.

-notch_gap

Specifies that the notch/gap is to be included in SPECIALNETS section. By default, -notch_gap option is off.

-pg_metal_fill

Specifies that the P/G metal fills are to be included in SPECIALNETS section. By default, -pg_metal_fill option is off.

-nets

Specifies that the NETS section is to be included in the output DEF file.

-routed_nets

Specifies that only routed nets are to be included in the SPECIALNETS and NETS sections. If this option is not specified, then all nets are included in the SPECIALNETS and NETS sections.

-diode_pins

Specifies that the diode (extra) pins are to be included in the NETS section. By default, -diode_pins option is on.

-floating_metal_fill

Specifies that the floating metal fill is to be included in the FILLS section. By default, -floating_metal_fill option is off.

-scanchain

Specifies that the SCANCHAINS section is to be included in the output DEF file. It can be combined with options for writing out other DEF sections.

-no_legalize

Specifies that name legalization should not occur. Name legalization escapes DEF special characters that do not actually have special meaning. Escaping the special character causes its special meaning to be ignored by the DEF reader. For example, if a component name contains bus bit characters, the bus bit characters will be escaped because it is not really a bus. By default, -no_legalize option is off.

-verbose

Enables the printing of additional debugging messages, of two types: those that contain information and those that contain warnings.

DESCRIPTION

The **write_def** command writes the design data of the specified design to a file in DEF format, including physical layout, netlist and design constrains.

NOTE: write_def uses the current_design from the current, open Milkyway design library. User need to open Milkyway design before write_def.

If none of **-rows_tracks_gcells**, **-vias**, **-regions_groups**, **-components**, **-macro**, **-fixed**, **-placed**, **-pins**, **-blockages**, **-specialnets**, **-nondefault_rule**, **-nets**, **-routed_nets**, **-diode_pins**, **-scanchain**, **-notch_gap**, **-floating_metal_fill**, and **-pg_metal_fill** are specified, all DEF sections are completely written out. Otherwise only the specified DEF sections are written out.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example writes out a file *out.def* from the existing design *top*.

```
prompt> write_def -output out.def
```

SEE ALSO

```
read_def(2)  
save_mw_cel(2)
```

write_design_lib_paths

Writes into a file the paths to which design libraries are mapped.

SYNTAX

```
status write_design_lib_paths
[-filename file_name]
[-dc_setup]
```

Data Types

file_name string

ARGUMENTS

-filename *file_name*
Specifies the file to which design library information is to be written. If **-dc_setup** is specified, the default file to which the data is written is **.synopsys_dc.setup** in the current working directory. If **-dc_setup** is not specified, the default file to which the data is written is determined by setting the **design_library_file** variable.

-dc_setup
Indicates that the *file_name* is to be written in **.synopsys_dc.setup** format. By default, the file is written in **synopsys_vss.setup** format (the format used by the Synopsys simulator). If **-dc_setup** is specified, the file written contains **define_design_lib** commands. The **-dc_setup** option changes the default *file_name* value to **.synopsys_dc.setup** in the current working directory.

DESCRIPTION

This command writes into a file the paths to which design libraries are mapped. The format is either **.synopsys_vss.setup** or **.synopsys_dc.setup**. The **write_design_lib_paths** command does not modify an existing file. If the file to which paths are written already exists, **write_design_lib_paths** fails.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, **write_design_lib_paths** writes the current design library paths:

```
prompt> write_design_lib_paths -file ~/.synopsys_dc.setup -dc_setup
```

SEE ALSO

`get_design_lib_path(2)`
`read_file(2)`
`report_design_lib(2)`

write_environment

Writes the variable settings and constraints for the specified cells or designs.

SYNTAX

```
return_val write_environment
[-cells cell_list | -designs design_list]
[-format dcsh | dctcl]
[-output file_name]
[-suffix suffix]
[-environment_only]
[-constraints_only]
[-no_lib_info]
[-consistency]
```

Data Types

<i>cell_list</i>	string
<i>design_list</i>	string
<i>file_name</i>	string
<i>suffix</i>	string

ARGUMENTS

-cells *cell_list*

The list of instances for which the environment is to be created. This option and the **-designs** option are mutually exclusive. You can specify one or the other or neither. If you specify neither, the command writes the environment for the current design.

-designs *design_list*

The list of designs for which the environment is to be created. This option and the **-cells** option are mutually exclusive. You can specify one or the other or neither. If you specify neither, the command writes the environment for the current design.

-format dcsh | dctcl

Specifies the format for the constraints file.

If you do not specify a format, the command uses Tcl format.

-output *file_name*

Specifies the output file name. If you specify the file name, this command generates a single file that contains the requested information. If you do not specify an output file name, this command creates an output file for each partition named *partition_name.suffix*, where the suffix value is determined by the **-suffix** option.

-suffix *suffix*

Specifies the output file suffix used by this command when you do not specify the file name. The default suffix is "env".

```
-environment_only
    Writes out only the variable settings. By default, both the variable settings
    and the constraints are written.

-constraints_only
    Writes out only the constraints. By default, both the variable settings and
    constraints are written.

-no_lib_info
    Specifies not to include attributes that come from library cells. By default,
    instances inherit attributes from their reference library cells.

-consistency
    Writes out variables, attributes, constraints etc. for consistency checking.
    When this option specified, -output option needs to be specified as well.
```

DESCRIPTION

For each specified design, this command writes out the following information:

- Settings for all variables whose settings have changed since the session began.
- Design constraints.
- Attributes inherited from the reference library cells

You can exclude information using the **-constraints_only**, **-environment_only**, and **-no_lib_info** options.

By default, an output file is generated for each design. You can generate a single output file by using the **-output** option.

Multicorner-Multimode Support

This command uses information from the current scenario only.

SEE ALSO

derive_constraints(2)

write_flip_chip_bumps

Write bump locations and connected nets to a specified AIF format file.

SYNTAX

```
status write_flip_chip_bumps
file_name
```

Data Types

file_name string

ARGUMENTS

file_name
Specifies the name of the output file.

DESCRIPTION

This command writes bump locations and net connections to a text file in the AIF format. The file can be specified with a relative or absolute path. The coordinates of the bump cells are referencing to the center of the die.

The following is an example of AIF file.

```
;This is a comment

Descriptions:

[DATABASE]

Identifies the file as an AIF file and contains the version and units of the coordinates.

[DIE]

Describes the width and height of the die and a name for the die. Width is measured along the horizontal X axis and height is measured along the vertical Y axis. The width and height are defined per die nominal described dimensions.

[PADS]

Defines all pad types needed for the die.

[NETLIST]

Defines each net and the coordinates of each die pad. Every column must have an entry.

If a particular data item is not present, a hyphen must be used as a placeholder.

EXAMPLES

The following example writes bump locations and net connections to the file bump_loc_net.

```
prompt> write_flip_chip_bumps ../scripts/bump_loc_net
```

SEE ALSO

DATA TYPES

nets_file string

ARGUMENTS:

```
-file_name nets_file
          Specifies the net file name. This is a required option.
```

DESCRIPTION

This command writes the flip-chip nets into a text file.

A flip-chip net is a net that connects a flip-chip driver I/O cell to a bump cell (which is also called a flip-chip pad).

EXAMPLES

The following example writes the flip-chip nets into a text file called flipChipNetFile.

```
prompt> write_flip_chip_nets -file_name flipChipNetFile
```

SEE ALSO

```

write_floorplan

Writes a Tcl script that can be used to recreate elements of the floorplan of the specified design.

SYNTAX

```
status write_floorplan
[-placement {io std_cell hard_macro soft_macro}]
[-create_terminal]
[-row]
[-track]
[-no_bound]
[-create_bound]
[-no_placement_blockage]
[-no_route_guide]
[-preroute]
[-no_plan_group]
[-no_voltage_area]
[-no_create_boundary]
[-pin_guide]
[-objects heterogeneous_collection]
[-all]
[-cell design_name]
[-sm_placement {io std_cell hard_macro soft_macro}]
[-sm_placement_blockage]
[-sm_route_guide]
[-sm_plan_group]
[-sm_voltage_area]
[-sm_bound]
[-sm_cell_row]
[-sm_track]
[-sm_preroute]
[-sm_all]
file_name
```

Data Types

<i>heterogeneous_collection</i>	collection
<i>design_name</i>	string
<i>file_name</i>	string

ARGUMENTS

-placement {io std_cell hard_macro soft_macro}
Write the specified placement information. The valid values are **io**, **std_cell**, **hard_macro**, and **soft_macro**. You can specify one or more of these values. If you specify the **io** value, you can also use the **-create_terminal** option. An I/O can be a terminal or a pad, depending on where this command is executed. If you specify the **soft_macro** value, black box cells are also output, because they are considered soft macros. By default, no placement information is written.

```
-create_terminal
    Write the create_terminal command for terminals. This option requires that
    the -placement {io} option is also specified.

-row
    Write the row information. By default, no row information is written.

-track
    Write the track information. By default, no track information is written.

-no_bound
    Do not write bound information. By default, bound information is written.

-create_bound
    Specifies to write "create_bounds" command instead of "update_bounds" for
    bound objects. This option does not take any effect if -no_bound option is
    specified.

-no_placement_blockage
    Do not write placement blockage information. By default, placement blockage
    information is written.

-no_route_guide
    Do not write route guide information. By default, route guide information is
    written.

-preroute
    Write preroute information. By default, no preroute information is written.

-no_plan_group
    Do not write plan group information. By default, plan group information is
    written.

-no_voltage_area
    Do not write voltage area information. By default, voltage area information
    is written.

-no_create_boundary
    Do not write boundary information. By default, boundary information is
    written.

-pin_guide
    Write pin guide information. By default, no pin guide information is written.

-objects heterogeneous_collection
    Specifies the objects to be written by write_floorplan. This option takes a
    collection that contains one or more of the following object types: cell
    instance, placement blockage, route guide, plan group, voltage area, bound,
    die area, core area, and cell row.
    The objects specified by this option are written only if their associated
    object type is enabled for output.

-all
    Write all floorplan information. You can use -no_xxx options together with
    this option to disable the writing of certain types of information. When using
```

-all, -create_terminal is ignored and always turn on.

-cell *design_name*
 Specifies the design name for which the floorplan information is written. By default, the floorplan information is written for the current design.

-sm_placement {*io std_cell hard_macro soft_macro*}
 Write the specified placement information for each soft macro. By default, no placement information is written for soft macros.

-sm_placement_blockage
 Write placement blockage information for each soft macro. By default, no placement blockage information is written for soft macros.

-sm_route_guide
 Write route guide information for each soft macro. By default, no route guide information is written for soft macros.

-sm_plan_group
 Write plan group information for each soft macro. By default, no plan group information is written for soft macros.

-sm_voltage_area
 Write voltage area information for each soft macro. By default, no voltage area information is written for soft macros.

-sm_bound
 Write bound information for each soft macro. By default, no bound information is written for soft macros.

-sm_cell_row
 Write cell row information for each soft macro. By default, no cell row information is written for soft macros.

-sm_track
 Write track information for each soft macro. By default, no track information is written for soft macros.

-sm_preroute
 Write preroute information for each soft macro. By default, no preroute information is written for soft macros.

-sm_all
 Write all floorplan information for each soft macro. By default, no floorplan information is written for soft macros.

file_name
 Specifies the name of the file to which to write the floorplan information.

DESCRIPTION

This command writes a Tcl script file that describes the floorplan information for the current design or the user-specified design. You restore the floorplan information by reading the generated file with the **read_floorplan** command.

The **write_floorplan** command writes commands relative to the top of the design, regardless of the current instance. The output file it writes must be read from the top of the design.

By default, the floorplan information is written only for the top-level design and includes the boundary information, as well as the following objects: bounds, placement blockages, route guides, plan groups, and voltage areas.

To output hierarchical information, you must specify **-sm_xxx** options.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command writes the floorplan to a file named top.fp and restores the floorplan by reading it.

```
prompt> current_mw_cel
"top"
prompt> write_floorplan -placement {io std_cell hard_macro} \
-row -track top.fp
1
prompt> read_floorplan top.fp
```

The following command writes all placed standard cells to a file called placed_std.fp.

```
prompt> write_floorplan -placement {std_cell} \
-objects [get_cells -filter "is_placed == true"] placed_std.fp
1
```

The following command writes a hierarchical floorplan that contains floorplan for each of the soft macros to a file called hier.fp.

```
prompt> write_floorplan -sm_all hier.fp
```

SEE ALSO

`current_mw_cel(2)`
`read_floorplan(2)`

write_interface_timing

Generates an interface timing ASCII report for a gate-level netlist or an interface logic model (ILM).

SYNTAX

```
int write_interface_timing  
file_name  
[-ignore_ports port_list]  
[-significant_digit digits]  
[-nosplit]
```

Data Types

<i>file_name</i>	string
<i>port_list</i>	list
<i>digits</i>	int

ARGUMENTS

<i>file_name</i>	Specifies the name of the file to which the interface timing information is to be written.
<i>-ignore_ports port_list</i>	Specifies a list of ports that are to be excluded from the timing file. By default, all ports are included.
<i>-significant_digit digits</i>	Specifies the number of digits to the right of the decimal point that are to be reported following the method used in the report_timing command. Allowed values are 0-13. The default value is 3. Use this option if you want to override the default. Fixed-precision floating-point arithmetic is used for delay calculation; thus the actual precision might depend on the platform.
<i>-nosplit</i>	The -nosplit option prevents line-splitting. This is most useful for doing diffs on previous scripts or for postprocessing the script.

DESCRIPTION

Generates an interface timing ASCII report for a gate-level netlist or an interface logic model (ILM). The report is a file containing interface timing information for a gate-level netlist or an ILM. The command performs an implicit **update_timing** if necessary for the selected data sections. A return code of **1** indicates that the command ran to completion; a **0** indicates an error.

You normally use the **compare_interface_timing** command to compare two report files that have been generated by the **write_interface_timing** command.

The output report file contains the following sections:

a) **Worst Slack Section** – Contains slack values of critical paths starting from input ports or ending at output ports. For each critical path, it reports slack values for following arc types: min_rise, min_fall, max_rise, max_fall.

b) **Type Section** – Contains worst-case max/min arc values for critical paths starting from input ports or ending at output ports. For each path timing relationship, it reports arc values for the following possible arc types: min_rise, min_fall, max_rise, max_fall.

EXAMPLES

The following example writes timing information for the current design to the *model.rpt* file.

```
prompt> write_interface_timing model.rpt
```

SEE ALSO

`compare_interface_timing(2)`
`update_timing(2)`

write_io_constraints

Writes an I/O constraints file.

SYNTAX

```
status write_io_constraints
[-library lib_name]
[-cell cell_name]
[-constraint_type side_only | side_order | side_location]
[-pin_only | -pad_only]
file_name
```

Data Types

<i>lib_name</i>	string
<i>cell_name</i>	string
<i>file_name</i>	string

ARGUMENTS

-library *lib_name*
Specifies the name of the library in which the Milkyway cell is open. If the library is open, you do not need to specify this option.

-cell *cell_name*
Specifies the name of the Milkyway cell from which the I/O constraints are extracted. If the Milkyway cell is open, you do not need to specify this option.

-constraint_type *side_only* | *side_order* | *side_location*
Specifies the constraint type. By default, this command writes side and location information in the I/O constraints file.
The supported values are mutually exclusive. Use only one.

- **side_only**
When **-constraint_type side_only** is specified, the command writes the side constraints based on the actual locations of the specified or current Milkyway cell into the constraints file.
- **side_order**
When **-constraint_type side_order** is specified, the command writes the side and order constraints based on the actual locations of the specified or current Milkyway cell into the constraints file.
- **side_location** (the default)
When **-constraint_type side_location** is specified, the command writes the side and location constraints based on the actual locations of the specified or current Milkyway cell into the constraints file. into file.

-pin_only
Specify this option to write only pin constraints.
This option should be used with the **-constraints** option. This option and the

```
-pad_only option are mutually exclusive; specify only one.  
  
-pad_only  
    Specify this option to write only pad constraints.  
    This option should be used with the -constraints option. This option and the  
    -pin_only option are mutually exclusive; specify only one.  
  
file_name  
    Specifies the name of the file to which the I/O constraints are written.
```

DESCRIPTION

This command writes the physical constraints information based on the actual locations of the specified or the current Milkyway cell to the specified file. The constraint file uses the Tcl format.

The contents in the database will not change. If the physical constraints based on the actual locations need to be stored in the database, use the **write_io_constraints** command to write the constraints to a file first, and then use the **read_io_constraints** command to read the constraints into the database from that file.

For the layer constraint, the **write_io_constraints** command writes the layer mask name.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example writes I/O constraints for the MULT16 Milkyway cell to a disk file called mult16.tcl.

```
prompt> write_io_constraints -lib design -cell MULT16 \  
-constraint_type side_order -pin_only mult16.tcl
```

SEE ALSO

```
read_io_constraints(2)  
report_io_constraints(2)  
remove_io_constraints(2)  
initialize_floorplan(2)
```

write_lib

Writes a compiled library to disk in Synopsys database, EDIF, or VHDL format.

SYNTAX

```
int write_lib
library_name
[-format db | edif | vhdl]
[-compress compression_format]
[-output file_name]
[-names_file file_list]
[-macro_only]
```

Data Types

library_name	string
file_name	string
file_list	list

ARGUMENTS

library_name

If you are writing in the Synopsys database (db) format, this argument specifies the name of the technology or symbol library to save. If you are writing in EDIF format, this argument specifies the name of the symbol library used to generate the EDIF library. If you are writing in VHDL format, the argument indicates the name of the technology library used to generate the VHDL library.

-format db | edif | vhdl

Specifies the external format of the specified library. The default is *db*, the Synopsys database format.

-compress compression_format

This option has effect only if the output format is db. For db format, only gzip is allowed as the *compression_format*, and a file name extension of .gz will be added if it is not already specified.

-output file_name

Specifies an output filename or pathname for the library.

-names_file file_list

When used in conjunction with the **-format edif** option, this option specifies a set of one or more name-mapping files. Design Compiler's EDIF writer uses this set of files to change the names of symbols or symbol pins in the incoming EDIF file (*file_name*) to resolve name-based consistency issues. If these files are required, you must create them before executing the **write_lib** command. When specifying more than one name-mapping file, enclose them in braces ({}).

-macro_only

When used for a physical library, this option allows only the macro

information being written out to Synopsys database format. And the physical technology information will not be written out. By default this option is off, and both technology information and macro information are written out to Synopsys database format.

DESCRIPTION

The **write_lib** command saves to disk a compiled technology or symbol library in db format.

For db format, if the **-output** option is used, the disk file is written to the specified filename. If **-output** is not used, the library is written to the current directory with filename *library_name.db*.

If the format is EDIF, **write_lib** takes a compiled symbol library, generates an EDIF library, and writes the library to disk.

The **-names_file** option for the **write_lib** command enables you to change the names of symbol and symbol pins. The general format of the name-mapping files is the same for the **write_lib** command as it is for the **change_names** command. The object types for the **write_lib** command are *reference* or *component* (to change symbol names), and *in* (to change symbol pin names).

The **-macro_only** option for the **write_lib** command enables you to write out only the macro information in a physical library to Synopsys database format. And the physical technology information will not be written out. By default this option is off, and both technology information and macro information are written out to Synopsys database format.

If the format is VHDL, **write_lib** takes a compiled technology library, generates a detailed VHDL library report, and library and writes the library to disk.

The VHDL library is configured based on the values of the following dc_shell or **lc_shell** environment variables:

```
vhdllib_architecture
vhdllib_glitch_handle
vhdllib_logic_system
vhdllib_logical_name
vhdllib_pulse_handle
vhdllib_tb_compare
vhdllib_tb_x_eq_dontcare
vhdllib_timing_checks
vhdllib_timing_mesg
vhdllib_timing_xgen
```

Based on the VHDL library configuration, the following files may be created:

- a components file with the name *library_name_components.vhd*
- a (VITAL) components file with the name *library_name_Vcomponents.vhd*
- a (VITAL) package file with the name *library_name_Vtables.vhd*
- an entity/architecture file with the name *library_name_FTGS.vhd*
- an entity/architecture file with the name *library_name_VITAL.vhd*

- an entire library testbench file with the name *library_name_tb.vhd*
- a testbench file for every cell with the name *library_name_cell_tb.vhd*
- an input stimulus file with the name *library_name_tb.sen*
- a verification script file with the name *library_name.csh*

If the **-output** option is used, the disk files are written with the specified principal and extension filename.

Before writing a library, you must first read the technology library file into the system using the **read_lib** command. **read_lib** automatically compiles the file and activates the **write_lib** command. Otherwise, the built-in security mechanism aborts **write_lib** before generating a VHDL library.

Note: This command overwrites files without warning.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reads and writes a technology library.

```
prompt> read_lib my_lib.lib
prompt> write_lib my_lib
```

The following example reads and writes a symbol library.

```
prompt> read_lib schem_lib.slib
prompt> write_lib schem_lib.sdb
```

The following example reads a symbol library and writes an EDIF symbol library.

```
prompt> read_lib schem_lib.slib
prompt> write_lib -f edif -output schem_lib.edif schem_lib.sdb
```

The following example writes a technology library to a specified file.

```
prompt> write_lib my_lib -output ~synopsys/test/test.db
```

The following example reads a technology library, sets the target architecture to FTGS, and writes a VHDL library as *my_lib_FTGS.vhd* and "my_lib_components.vhd". The log report is redirected to *my_lib.LOG*.

```
prompt> read_lib mylib.lib
prompt> vhdllib_architecture=FTGS
prompt> write_lib -f vhdl my_lib > my_lib.LOG
```

The following example reads a technology library, sets the target architecture to FTGS, and writes a VHDL library to files, *spec_FTGS.vhd* and *spec_components.vhd*. A log file is displayed.

```
prompt> read_lib mylib.lib
prompt> vhdllib_architecture=FTGS
prompt> write_lib -f vhdl -output spec.vhd my_lib
```

The following example shows a name-mapping file called lib.names and its usage.

Design	Type	Old Name	New Name
lib	reference	NR2	nr2
NR2	pin A	a	
NR2	pin B	b	
NR2	pin Z	z	
lib	reference	HO22	aoi2
HO22	pin I1	a	
HO22	pin I2	b	
HO22	pin I3	c	
HO22	pin O1	z	

```
prompt> read_lib foo.slib
prompt> write_lib foo -format EDIF -names_file lib.names -o foo.edif
```

SEE ALSO

[compare_lib\(2\)](#)
[read_lib\(2\)](#)

write_link_library

Writes shell commands to save the current link library settings for design instances.

SYNTAX

```
int write_link_library
[-full_path_lib_names] [-nosplit]
[-full_path_lib_names] [-nosplit]
[-output file_name]
[-target target]
```

Data Types

<i>file_name</i>	string
<i>target</i>	string

ARGUMENTS

- full_path_lib_names
 - Writes library names with full pathnames. The default is to write only the library name without the path.
- nosplit
 - Indicates that lines are not to be split when column fields overflow. This is most useful for diffing on previous scripts or for post-processing the script.
- output *file_name*
 - Writes the script to the specified file. By default, the command writes shell commands to standard output.
- target *target*
 - Specifies the target to write out scripts. The only valid value is **ptsh**.

DESCRIPTION

This command writes a script of shell commands. It is used to recreate link library settings for each instance in the design.

The redirection operator (>) can be used to redirect the output of this command to a disk.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows output redirected to a file named *output.tcl* and uses the full pathname for output for the link libraries.

```
prompt> write_link_library -output output.tcl \
-full_path_lib_names
```

SEE ALSO

[link_library\(3\)](#)

write_mw_lib_files

Writes the technology, or plib, or reference control file of the Milkyway library.

SYNTAX

```
status_value write_mw_lib_files
[-technology]
[-plib]
[-reference_control_file]
-output file_name
libName
```

Data Types

<i>file_name</i>	string
<i>libName</i>	string

ARGUMENTS

-technology
Indicates to dump technology information.
This option and the **-plib** option, the **-reference_control_file** option are mutually exclusive.

-plib
Indicates to dump plib file.
This option and the **-technology** option, the **-reference_control_file** option are mutually exclusive.

-reference_control_file
Indicates to dump the reference control file.
This option and the **-technology** option, the **-plib** option are mutually exclusive.

-output *file_name*
Specifies the file name in which the technology information or the reference library information is stored.

libName
Specifies the Milkyway library to be reported.

DESCRIPTION

Dumps the technology information or the reference library information to an ASCII file that you can edit.

At least one of the **-technology**, or **-plib**, or the **-reference_control_file** options must be specified.

A status indicating success or failure is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example displays unit information about a Milkyway library:

```
prompt> write_mw_lib_files -reference_control_file -output ref.out design  
1
```

SEE ALSO

`create_mw_lib(2)`
`set_mw_lib_reference(2)`
`set_mw_technology_file(2)`

write_parasitics

Writes parasitics to a disk file for delay calculation tools.

SYNTAX

```
status write_parasitics
[-output file_name]
[-format SPEF | SBPF]
[-compress]
[-routed_nets_only]
[-no_name_mapping]
```

Data Types

file_name string

ARGUMENTS

-output *file_name*

Specifies the name of the output file to which parasitics for the current design are written. If you do not specify this option, the following naming convention is used for the output file name:

design_name.format_name.

In the multicorner-multimode flow while writing the parasitic file, the tool uses the name of the tluplus file and the temperature associated with the corner, along with the file name you specified, to derive the file name of the parasitic file.

If you specify the scaling factors for capacitance, resistance and coupling capacitance by using the **set_extraction_options** command you will see a scaling section in the output file name.

The naming convention used by the tool is in the following format:

<tluplus file name>.<temperature>.<user scaling>

The number in the scaling section <user scaling> is in the following format:

<res>_<cap>_<ccap>

where *design_name* is the name of the current design.

-format SPEF | SBPF

Specifies whether to write parasitics in Standard Parasitic Exchange Format (SPEF) or Standard Binary Format (SBPF) format. If you do not specify this option, parasitics are written in SPEF format.

-compress

Specifies that the generated SPEF file is to be compressed in gzip format. The name of the compressed file will then be the name of the output file with .gz appended to the file name. This option is valid only when you write parasitics in SPEF format. By default, output is not compressed.

-routed_nets_only

Writes parasitics only for fully routed nets. By default, parasitics are

output for both routed and unrouted nets. Use this option to revert to the default behavior of versions prior to A2007.12.

-no_name_mapping

Specifies whether the net name will be used directly in the file. This option is valid only when you write parasitics in SPEF format. With no name mapping, the actual net names are used in the .spef file. With name mapping, the net names are mapped to numbers that are later used when writing RC details.

DESCRIPTION

This command writes parasitics for the current design to a disk file.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following example writes parasitics for all the nets in the current design. If there are minimum and maximum operating conditions and the output format is SPEF, parasitics for both conditions are written.

```
prompt> write_parasitics -format spef -output top
```

write_physical_constraints

Writes floorplan information in Tcl format for use in Design Compiler topographical mode.

SYNTAX

```
status write_physical_constraints
      -output tcl_file
      [-port_side]
```

Data Types

tcl_file string

ARGUMENTS

```
-output tcl_file
        Specifies the name of the file to which the physical constraints are written.
        This argument is required.

-port_side
        In addition to writing out the default floorplan information, the command
        also writes port side constraints if this option is specified.
```

DESCRIPTION

Writes floorplan information in Tcl format to the specified file. This file is for use in Design Compiler topographical mode. The default floorplan information includes: core area, port locations, I/O pad locations and orientations, macro locations and orientations, and placement blockages.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example writes floorplan information to the file named a.out:

```
prompt> write_physical_constraints -output a.out
```

The following example writes floorplan information and port side constraints to the file named b.out:

```
prompt> write_physical_constraints -output b.out -port_side
```

SEE ALSO

```
create_bounds(2)
create_net_shape(2)
create_placement_blockage(2)
create_site_row(2)
create_voltage_area(2)
set_cell_location(2)
set_port_location(2)
```

write_physical_script

Writes a Tcl script to save the current physical settings.

SYNTAX

```
status write_physical_script
-mpc
-nosplit
-output file_name
```

ARGUMENTS

```
-mpc
    Write out only the mpc constraints

-nosplit
    Do not split each command if long to multiple lines, default is to split into
    multiple lines.

-output file_name
    Indicates that the script is to be written to the specified file.
```

DESCRIPTION

The **write_physical_script** command writes a Tcl script that recreates the physical attributes on the current design.

User-defined attributes are not supported. Attributes and objects created by the following commands are supported:

```
set_floorplan_options
set_floorplan_pnet_options
set_floorplan_port_options
set_floorplan_macro_options
set_floorplan_macro_array
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, the settings on the current design are written to the file test.scr.

```
prompt> write_physical_script -mpc -output test.scr
```

SEE ALSO

`current_design(2)`
`reset_design(2)`
`write(2)`

write_plib

Writes the library data of the specified library to a file in Synopsys physical library (.plib) format.

SYNTAX

```
int write_plib
[-lib_name lib_name]
[-cell_name cell_name]
[-ignore_tech_info]
[-signal_em_only]
[-antenna_rule_only]
[-cell_info]
[-ignore_cell_geom]
[-antenna_prop_only]
[-metal_density_only]
[-basic_cell_pin_info_only]
plib_file_name
```

Data Types

<i>lib_name</i>	string
<i>cell_name</i>	string
<i>plib_file_name</i>	string

ARGUMENTS

-lib_name *lib_name*
Specifies the Milkyway library that contains the design cell. The *lib_name* can include the path of the library. If it does not, the library is resolved from the current working directory.

-cell_name *cell_name*
Specifies the cell names that physical layout information is written to in the macro section of the .plib file. These cells should exist in the FRAM view. If you want to write multiple cells, you should delimit the cell name list by using quotation marks ("") and separate the names with a comma (,). For example, the *cell_name* argument could be "AND2, BUFF2".

-ignore_tech_info
Causes technology information *not* to be written out. By default, the command writes out technology information to the .plib file.

-signal_em_only
Writes out only signal EM information.

-antenna_rule_only
Writes out only antenna rules information.

-cell_info
Writes out cell information. By default, the command does not write out cell information to the .plib file.

```
-ignore_cell_geom
    Causes the command not to write out all cell geometries. Cell information
    includes only macro attributes and pin attributes. By default, when the -cell_info
    option is specified, the command writes out physical cell layout
    information to the .plib file.

-antenna_prop_only
    Writes out only antenna property information.

plib_file_name
    Specifies the name of the .plib file to which the command writes library
    information. If the file already exists, the command overwrites it. If the
    file does not exist, the command creates it. The plib_file_name argument can
    include the path of the output file. If it does not, the file is written to
    the current working directory.
```

DESCRIPTION

This command writes the library data of the specified library to a file in .plib format.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example writes out a complete .plib file named *outplib* from a library named *cells*.

```
prompt> write_plib -lib_name cells -cell_info outplib
```

SEE ALSO

`write_mw_lib_files(2)`

write_qtm_model

Writes the Quick Timing Model (QTM) file.

SYNTAX

```
string write_qtm_model
-out_dir output_qtm_directory
[-text]
```

Data Types

output_qtm_directory string

ARGUMENTS

```
-out_dir output_qtm_directory
    Specifies the name of the output QTM directory

-text
    To write out text format file for the QTM model in addition to the .db format
    file.
```

DESCRIPTION

This command writes out the QTM model file in Synopsys .db format.

If the *-text* option is provided then the QTM model file is written out in text format also.

This command writes out all the QTM Model(s) in the internal QTM database with different names in one output directory. You must provide the output directory as a command-line option.

The name of the QTM Model is given in **create_qtm_model** command. The name of the output QTM Model file is derived from the QTM Model Name. The output QTM Model file name is *<ModelName>.qtm.db*.

This command writes out the in-memory .db to on-disk .db file. This command runs slower than **save_qtm_model** command and requires disk I/O. Usually, this command is expected to be called once at the end of an ICC session to get a final version of the QTM model.

For a more detailed description about QTM please refer to the *ICC Design Planning User Guide*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example writes the QTM Model **adder** in internal QTM database in directory **qtm** as **adder.qtm.db**. This will generate a file **./qtm/adder.qtm.db**

```
prompt> write_qtm_model -out_dir qtm
```

SEE ALSO

`create_qtm_model(2)`
`save_qtm_model(2)`

write_route

Writes the routing information to the specified file.

SYNTAX

```
status write_route
    -output file_name
    [-nets collection_of_nets]
    [-skip_route_guide]
    [-output_metal_fill]
    [-objects collection_of_objects]
```

ARGUMENTS

```
-output file_name
    Specifies the output file name. Routing information is written to file_name.
    This is a required argument.

-nets collection_of_nets
    Specifies the collection of nets for which to write out routing information.
    If you specify more than one net, separate them with a space.
    If you do not use the -nets option, the default is to write out all routing
    information.

-skip_route_guide
    Do not write route guide information to the output file. By default, route
    guide information is written.

-output_metal_fill
    Write metal fill information to the output file. By default, metal fill
    information is not written.

-objects collection_of_objects
    Specifies a collection of wires and/or vias. The -nets and -objects are
    mutually exclusive.
```

DESCRIPTION

The **write_route** command outputs the routing information as a set of tcl commands to the specified file. Users can source the file back into IC Compiler.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples write the routing information to a file called my_route.txt.

```
prompt> write_route -output my_route.txt
```

```
prompt> write_route -objects [get_selection] -output my_route.txt
```

SEE ALSO

```
write_def(2)
create_net_shape(2)
create_via(2)
create_user_shape(2)
create_route_guide(2)
```

write_rp_groups

Writes out the relative placement constraints for the specified relative placement groups.

SYNTAX

```
collection write_rp_groups
rp_groups | -all
[-hierarchy]
[-quiet]
[-nosplit]
[-output filename]
[-create]
[-leaf]
[-keepout]
[-instance]
[-include]
```

Data Types

<i>rp_groups</i>	list or collection
<i>filename</i>	string

ARGUMENTS

rp_groups

Specifies the relative placement groups to be written out to the script.
This option is mutually exclusive with the **-all** option.

-all

Specifies that all relative placement groups are to be written out to the generated script.
This option cannot be used with either the *rp_groups* argument or the **-hierarchy** option.

-hierarchy

Specifies that all relative placement groups within the hierarchy of the groups in *rp_groups* are to be written out. By default, subgroups are not written out.
This option is mutually exclusive with the **-all** option.

-quiet

Turns off informational messages that would otherwise be issued if no groups are written.

-nosplit

Specifies not to split long commands into multiple lines. The default is to split long commands into multiple lines.

-output *filename*

Specifies that the script is to be written to *filename*. The default is to write to standard output.

```

-create
    Specifies that the create_rp_group commands are included in the generated
    script.

-leaf
    Specifies that the add_to_rp_group -leaf commands are included in the
    generated script.

-keepout
    Specifies that the add_to_rp_group -keepout commands are included in the
    generated script.

-instance
    Specifies that the add_to_rp_group -hierarchy -instance commands are included
    in the generated script.

-include
    Specifies that the add_to_rp_group -hierarchy commands (without -instance)
    are included in the generated script.

```

DESCRIPTION

The **write_rp_groups** command writes the relative placement constraints for the specified relative placement groups. You can use the generated commands to recreate the relative placement groups and their items on the same designs.

When you specify any of the **-create**, **-leaf**, **-keepout**, **-instance**, and **-include** options, the generated script contains only the commands related to the specified options. If you do not specify any of these options, all commands are output to the generated script.

The command returns a collection that contains the relative placement groups that are written out. If no objects are written out, the empty string is returned.

Relative placement usage is available with Design Compiler Ultra.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **write_rp_groups** to recreate relative placement groups after their removal:

```

prompt> get_rp_groups
{mul::grp_mul ripple::grp_ripple example3::top_group}

prompt> write_rp_groups -all-out my_groups.tcl
{mul::grp_mul ripple::grp_ripple example3::top_group}

```

```
prompt> remove_rp_groups -all -quiet
1

prompt> get_rp_groups
Error: Can't find objects matching '''. (UID-109)

prompt> source my_groups.tcl
{example3::top_group}

prompt> get_rp_groups
{example3::top_group ripple::grp_ripple mul::grp_mul}
```

SEE ALSO

`add_to_rp_group(2)`
`create_rp_group(2)`
`remove_rp_groups(2)`

write_script

Writes shell commands to save the current settings.

SYNTAX

```
int write_script
[-no_annotated_check] [-no_annotated_delay] [-no_cg]
[-full_path_lib_names] [-nosplit]
[-format dctcl | dcsh]
[-include loop_breaking]
[-output file_name]
```

ARGUMENTS

-no_annotated_check

Indicates that **set_annotated_check** commands are not to be written. By default, annotation commands are written to standard output. Use this option to avoid creating a very large script for designs that contain a large amount of annotated information. Annotated timing checks can be written to a file using the **write_timing** command.

-no_annotated_delay

Indicates that **set_annotated_delay** commands are not to be written. By default, annotation commands are written to standard output. Use this option to avoid creating a very large script for designs that contain a large amount of annotated information. Annotated delays can be written to a file using the **write_timing** command.

-no_cg

Indicates that Power Compiler clock gating attributes are not to be written. By default, **set_attribute** commands are written to standard output for all relevant clock gating attributes. Use this option if clock gate information is not needed for later flow.

-full_path_lib_names

Indicates that library names are to be written with full pathnames. The default is to write only the library name, without the path.

-nosplit

Indicates that lines are not to be split when column fields overflow. This is most useful for doing diffs on previous scripts, or for post-processing the script.

-format dctcl | dcsh

Indicates that the script is to be written in Tcl mode or dcsh mode.

-include loop_breaking

Write the **set_disable_timing** commands for internally disabled timing arcs.

-output *file_name*

Indicates that the script is to be written to the specified file.

DESCRIPTION

The **write_script** command writes a script of dc_shell commands. This command is used to recreate the attributes on the current design.

By default, the **write_script** command writes dc_shell commands to standard output.

The redirection operator (>) can be used to redirect the output of this command to a disk file.

User-defined attributes are not supported. Attributes and objects created by the following dc_shell commands are supported:

```
create_clock
group_path
set_annotated_check
set_annotated_delay
set_boundary_optimization
set_disable_timing
set_dont_retime
set_dont_touch
set_dont_touch_network

set_ungroup
set_wire_load_model
set_wire_load_mode
set_wire_load_selection_group
set_wire_load_min_block_size
set_wired_logic_disable
```

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

In the following example, the settings on the current design are written to the file test.scr.

```
prompt> write_script > test.scr
```

In the following example, the settings on the current design are written to standard output. An example of the output file is also provided.

```
prompt> write_script
*****
Created by write_script() on Fri Jun 21 17:57:25 1991
*****
/* Set the current_design */
current_design TOP

set_operating_conditions WCCOM
set_wire_load_model WL_SMALL_BLOCK
create_clock -period 100 -waveform {0 5} [get_ports c1]
set_input_delay 1.5 -clock c1 [get_ports B]
set_input_delay 2.8 -clock c1 [get_ports A]
```

SEE ALSO

```
current_design(2)

write(2)
```

write_sdc

Writes out a script in Synopsys Design Constraints (SDC) format.

SYNTAX

```
int write_sdc
file_name
[-nosplit]
[-version sdc_version]
```

Data Types

file_name string

ARGUMENTS

file_name
Specifies the name of the file to which the SDC script is to be written.

-nosplit
Indicates that lines are not to be split when column fields overflow. This is most useful when comparing previous script files with the UNIX diff command, or for post-processing the script.

-version sdc_version
Specifies the version of SDC to write. Allowed values are **1.2**, **1.3**, **1.4**, **1.5**, **1.6**, **1.7**, and **latest** (the default).

DESCRIPTION

The **write_sdc** command writes out a script file in the latest Synopsys Design Constraints (SDC) format. This script contains commands that can be used with PrimeTime or with Design Compiler. SDC is also licensed by external vendors through the Tap-in program. SDC-formatted script files are read into PrimeTime or Design Compiler using the **read_sdc** command.

By default, the script is written as simple text. Also, by default the latest version of SDC is written. Some earlier versions of SDC can be written using the **-version** option.

SDC is a subset of the commands already supported by Design Compiler, Physical Compiler, IC Compiler, Astro, Jupiter, and PrimeTime. Of the commands supported in the latest SDC version, the following may be written by **write_sdc**. Those added for versions 1.3 and later are noted.

General Purpose Commands:

```
expr
list
set
```

Object Access Functions:

```
all_clocks
all_inputs
all_outputs
all_registers (1.7)
current_design
current_instance
get_cells
get_clocks
get_libs
get_lib_cells
get_lib_pins
get_nets
get_pins
get_ports
set_hierarchy_separator
```

Basic Timing Assertions:

```
create_clock
create_generated_clock (1.3)
group_path (1.7)
set_clock_gating_check
set_clock_groups (1.7)
set_clock_latency
set_clock_sense (1.7)
set_clock_transition
set_clock_uncertainty
set_false_path
set_ideal_latency (1.7)
set_ideal_transition (1.7)
set_input_delay
set_max_delay
set_min_delay
set_multicycle_path
set_output_delay
set_propagated_clock
```

New options to existing supported commands:

```
create_clock -add (1.4)
create_generated_clock -add (1.4)
create_generated_clock -master_clock (1.4)
create_generated_clock -combinational (1.7)
```

Secondary Assertions:

```
set_disable_timing
set_max_time_borrow
```

Environment Assertions:

```
create_voltage_area (1.6)
set_case_analysis
```

```
set_drive
set_driving_cell
set_fanout_load
set_input_transition
set_ideal_network (1.7)
set_level_shifter_strategy (1.6)
set_level_shifter_threshold (1.6)
set_load
set_logic_dc
set_logic_one
set_logic_zero
set_max_area
set_max_capacitance
set_max_dynamic_power (1.4)
set_max_fanout
set_max_leakage_power (1.4)
set_max_transition
set_min_capacitance
set_min_fanout
set_min_porosity (1.4)
set_operating_conditions
set_port_fanout_number
set_resistance
set_wire_load_min_block_size
set_wire_load_mode
set_wire_load_model
set_wire_load_selection_group
```

Like **write_script**, the **write_sdc** command writes out commands relative to the top of the design, regardless of the current instance. SDC files written by **write_sdc** must be read in from the top of the design.

For a complete guide to using SDC with Synopsys applications, see the *Using the Synopsys Design Constraints Format Application Note* which is available through SolvNET at <http://solvnet.synopsys.com>.

The usage of some of the supported commands is restricted when reading SDC. In some cases, some options are not allowed. The **write_sdc** command supports the restricted usage by restricting what is written. The following restrictions apply for SDC Version 1.3:

- For **set_driving_cell**, the **-min** and **-max** options are not supported.
- For **set_port_fanout_number**, the **-min** and **-max** options are not supported.

When the hierarchy has been partially flattened, embedded hierarchy separators can make names ambiguous. It is not clear which hierarchy separator characters are part of the name, and which are real separators. Beginning with SDC Version 1.2, hierarchical names can be made non-ambiguous using the **set_hierarchy_separator** SDC command and/or the **-hsc** option available on the **get_cells**, **get_lib_cells**, **get_lib_pins**, **get_nets**, and **get_pins** SDC object access commands. By default, PrimeTime and Design Compiler write an SDC file using these features to create non-ambiguous names. It is considered best practice to write SDC files that contain

names that are not ambiguous. However, if you are using a third-party application that does not fully support SDC 1.2 or later (that is, it does not support the non-ambiguous hierarchical names features of SDC), then you can suppress these features by setting **sdc_write_unambiguous_names** variable to **true**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command writes the SDC script to the file named *top.sdc*:

```
prompt> write_sdc top.sdc
1
```

SEE ALSO

`read_sdc(2)`
`write_script(2)`
`sdc_write_unambiguous_names(3)`

write_sdf

Writes a Standard Delay Format (SDF) back-annotation file.

SYNTAX

```
string write_sdf
[-version sdf_version] [-significant_digits digits]
[-instance inst_name]
file_name
```

Data Types

<i>sdf_version</i>	string
<i>inst_name</i>	string
<i>file_name</i>	string

ARGUMENTS

```
-version sdf_version
    Selects which SDF version to use. Supported SDF versions are 1.0 or 2.1. SDF
    2.1 is the default.

-significant_digits digits
    Specifies the number of digits to the right of the decimal point that are
    reported. Allowed values are from 0 through 13; the default is 3. Using this
    option overrides the value set by the variable
    report_default_significant_digits.

-instance inst_name
    Specifies that the SDF is to be written only for the instance named inst_name.

file_name
    Specifies the name of the SDF file to write.
```

DESCRIPTION

Writes leaf cell pin-to-pin timing information to a disk file. Timing information is written in SDF format using version v1.0 or v2.1. The timing file contains data associated with the netlist from which it is created.

Use **write_sdf** only when the instance names in the design agree with the naming conventions of the system to which the timing file is written.

Timing information can be written in multiples of ns, ps, and us. The time unit in the SDF file is the time unit specified in the technology library and is written in the timing file under 'timescale'. If there is no time unit in the library, the unit is assumed to be a multiple of nanoseconds.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example writes timing information for the design **MULT16** to a disk file called **mult16.sdf**, using SDF version 2.1.

```
prompt> write_sdf -version 2.1 mult16.sdf
```

SEE ALSO

```
read_sdf(2)
set_annotated_check(2)
set_annotated_delay(2)
remove_annotated_check(2)
remove_annotated_delay(2)
report_annotated_check(2)
report_annotated_delay(2)
report_default_significant_digits(3)
```

write_stream

Writes a design (library) into a GDSII or Oasis file.

SYNTAX

```
status write_stream
[-lib_name lib_name]
[-format gds | oasis]
[-cells list_of_cells]
[-cell_file cell_name_file]
stream_file_name
```

ARGUMENTS

-lib_name *lib_name*

Specifies the library name which contains the layout cells. If not specified, the current opened library is used.

-format gds | oasis

Format of output file. The value must be gds or oasis. Default format is gds.

-cells *list_of_cells*

Specifies the cell names to be output. If not specified, write_stream outputs all the cells in the specified library.

-cell_file *cell_name_file*

Specifies the name of the file that contains the cell names to be output. This option is for GDS only.

stream_file_name

Specifies the file name where to write library data. This is a required argument.

DESCRIPTION

Command **write_stream** writes the data in specified library to a file in GDS or OASIS format. The options are set by **set_write_stream_options** and reported by **report_write_stream_options**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example writes out the existing library "design" into a file "out.gds".

```
prompt> write_stream -lib_name design -format gds out.gds
or
```

write_stream
2916

```
prompt> write_stream -lib_name design out.gds
```

SEE ALSO

`set_write_stream_options(2)`
`report_write_stream_options(2)`

write_verilog

Outputs a hierarchical Verilog file for the current design.

SYNTAX

```
status write_verilog
[-pg]
[-split_bus]
[-empty_module]
[-no_physical_only_cells]
[-no_pg_pin_only_cells]
[-no_corner_pad_cells]
[-no_pad_filler_cells]
[-no_core_filler_cells]
[-no_flip_chip_bump_cells]
[-no_cover_cells]
[-no_chip_cells]
[-no_io_pad_cells]
[-no_tap_cells]
[-no_unconnected_cells]
[-unconnected_ports]
[-keep_backslash_before_hiersep]
[-diode_ports]
[-wire_declaration]
[-output_net_name_for_tie]
[-macro_definition]
[-force_output_references reference_names]
[-force_no_output_references reference_names]
verilog_file_name
```

Data Types

<i>reference_names</i>	string
<i>verilog_file_name</i>	string

ARGUMENTS

-pg

Output power and ground nets and ports for all cell instances and module instances.

By default, the power and ground ports are ignored.

-split_bus

Outputs bus ports as individual bits. The port names are treated as scalar port names and are escaped.

For example, if you have the following module definition,

```
module top (out, in);
```

```
    output [3:0] out;
```

```
    input in;
```

```
    ...
```

```
endmodule
```

It is output as

```

module top(\out[3] , \out[2] , \out[1] , \out[0] , in);
    output \out[3] ;
    output \out[2] ;
    output \out[1] ;
    input \out[0] ;
    output in;
    ...
endmodule

-empty_module
Output empty module definitions for leaf-level cells, such as standard cells and macro cells. These module definitions contain port definitions but no internal module instances.
By default, no module definitions are written for leaf-level cells.

-no_physical_only_cells
Do not output physical-only cell instances. When you specify this option, the behavior is the same as when all the following options are specified: -
no_pg_pin_only_cells -no_corner_pad_cells -no_pad_filler_cells -no_core_filler_cells -no_chip_cells -no_tap_cells

-no_pg_pin_only_cells
Do not output cell instances that do not fall in the other five subtypes of physical-only cells and have only power or ground pins.

-no_corner_pad_cells
Do not output corner pad cell instances.

-no_pad_filler_cells
Do not output pad filler cell instances.

-no_core_filler_cells
Do not output core filler cell instances.

-no_flip_chip_bump_cells
Do not output flip-chip bump cell instances.

-no_cover_cells
Do not output cover cell instances.

-no_chip_cells
Do not output chip cell instances.

-no_io_pad_cells
Do not output I/O pad cell instances.

-no_tap_cells
Do not output tap cell instances.

-no_unconnected_cells
Do not output unconnected cell instances. Unconnected cell instances are instances with no ports connected except for power and ground ports.

-unconnected_ports
Output unconnected ports on module instances, macro instances, and standard

```

cell instances. All unconnected ports are output with a "SYNOPSYS_UNCONNECTED_%d" net. The "%d" portion of the name represents the unconnected net number, which is incrementally increased every time a net is generated for uniqueness.

By default, the unconnected ports are ignored.

-keep_backslash_before_hiersep

Keep the backslash character preceding a hierarchy separator for all identified instances.

By default, the backslash character is removed.

-diode_ports

Output diode ports for cell instances.

By default, the diode ports are ignored.

-wire_declaration

Output wire declarations in the hierarchical Verilog description. This option controls only the scalar wires. For bus wires, a declaration with bus limits is output regardless of this option.

By default, the command outputs wire declarations only for buses.

For example, if you use **-wire_declaration**, the wires are written as
wire n246;

wire [1:0] n245;

BUF U12 (.A(n245[0]), .Y(n246));

If you do not use **-wire_declaration**, the wires are written as

wire [1:0] n245;

BUF U12 (.A(n245[0]), .Y(n246));

-output_net_name_for_tie

Output an indirect tie net as its net name and a direct tie net that has a name of SNPS_LOGIC1 or SNPS_LOGIC0 as 1'b1 or 1'b0, respectively.

By default, both direct and indirect tie nets are written out as 1'b1 for logic 1 or 1'b0 for logic 0.

-macro_definition

Output module definitions for soft macros. A soft macro is a user-partitioned macro that is generated during design planning. Most big designs tend to be divided into several partitioned macros. When you use this option, the Verilog writer looks inside the soft macro and outputs the internal details. The full contents of ILM blocks are also output.

By default, a soft macro is treated as a leaf macro and its definition is not output.

-force_output_references reference_names

Specifies the reference cell names, separated with a space, for which all cell instances must be output, overriding the following options:

-no_physical_only_cells
-no_pg_pin_only_cells
-no_corner_pad_cells
-no_pad_filler_cells
-no_core_filler_cells
-no_tap_cells
-no_cover_cells
-no_chip_cells
-no_flip_chip_bump_cells

```

-no_io_pad_cells
-no_unconnected_cells
The maximum allowed string size is 1023 chars.

-force_no_output_references reference_names
Specifies the reference cell names, separated with a space, for which all
cell instances must not be output, overriding the same options as listed for
-force_output_references.
For example, consider a cell "top" with four types of core filler cells:
FILL1, FILL2, FILL4, and FILL8. To generate the Verilog description with only
FILL4 and FILL8 instances, use the -no_core_filler_cells option and specify
-force_output_references FILL4 FILL8.

```

DESCRIPTION

This command generates a Verilog netlist for the current Milkyway design. By specifying different options, you can control the behavior of this command.

Before running the **write_verilog** command, you should always run the **change_names -rule verilog -hierarchy** command. This command ensures correct Verilog naming conventions and also identifies the power switches present in the design.

If you run the **change_names** command before running **write_verilog**, the power switches are not output in the Verilog netlist. Otherwise, power switches are output by using supply1 statements.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the most common use of the **write_verilog** command.

```

prompt> write_verilog top_hvo.v
Generating description for top level cell.
Processing module sub
Processing module top
Elapsed = 0:00:00, CPU = 0:00:00
Write verilog completed successfully.

```
